Intestine

2960 CIRCADIAN RHYTHM OF GLYCOGEN IN THE SMOOTH MUSCLE OF THE LARGE INTESTINE OF FED AND STARVED IMMATURE RATS. (Eng.) Hoopes, P. C.; Bo, W. J.; Krueger, W. A. (Bowman Gray Sch. Medicine, Wake Forest Univ., Winston-Salem, NC 27103). *Nutr. Rep. Int.* 14(5):521-525; 1976.

The glycogen concentration in the smooth muscle of the rat large intestine was investigated at 3-hr intervals over a 24-hr period. The animals were either allowed food *ad libitum* or starved 36 hr prior to autopsy. For fed rats, the peak glycogen concentration (1.02 ± 0.08 μg/mg) occurred at 2400 hr, while the low value (0.52 ± 0.06 μg/mg) was observed at 1500 hr. The difference between low and high points represented an increase of 96%. In rats starved for 36 hr, the peak glycogen concentration (1.54 ± 0.17 μg/mg) occurred at 0600 hr and a low (0.55 ± 0.10 μg/mg) appeared at 2400 hr. The increase between low and high points for starved rats was 180%. The data indicate that a circadian rhythm is present in the rat large intestine, which continues under conditions of starvation, although an apparent phase shift takes place.

2961 STIMULATION OF SODIUM AND WATER SECRETION WITHOUT INHIBITION OF GLUCOSE ABSORPTION IN THE RAT JEJUNUM BY VASOACTIVE INTESTINAL PEPTIDE (VIP). (Eng.) Coupar, I. M. (Dept. Pharmacology, Monash Univ., Wellington Rd., Clayton 3168, Victoria, Australia). *Clin. Exp. Pharmacol. Physiol.* 3(6):615-618; 1976.

The potency of vasoactive intestinal peptide (VIP) as a stimulant of small intestinal fluid secretion was estimated *in vivo* in the rabbit, and its possible ability to inhibit active glucose absorption was tested. VIP was slowly infused (0.035 ml/min) into the superior mesenteric artery for 30 min, and the jejunal lumen was perfused during the last 20 min with a solution containing 154 Na$^+$, 154 Cl$^-$, 5.5 D(+)-glucose, and phenosulphonphthalein. Glucose absorption and the perfusion pressure in the superior mesenteric artery were not significantly altered by the infusion of VIP. However, the infusion did produce a large net secretion of Na$^+$ and water into the lumen of the jejunum. During a control infusion with saline into the arterial blood, the jejunum absorbed a net amount of Na$^+$ and water (mean, +8.3 μmol/g/20 min and +10.9 mmol/g/20 min); when VIP (4 x 10^{-11} μmol/min) was infused, this was changed to a net secretion (-54.8 μmol/g/20 min for Na$^+$, -21.3 mmol/g/20 min for water). Increasing the infusion rate to 2 x 10^{-10} μmol/min resulted in an increased secretion rate of -87.8 μmol/g/20 min Na$^+$ and -33.9 mmol/g/20 min water. This study confirms that continuous infusion of VIP does not significantly affect the mesenteric vascular bed of the rat, as in the dog, although the amounts infused were biologically activ and caused a large fluid secretion into the lumen. This is the first demonstration of fluid secretion produced by VIP in the rat.

2962 TRANSMISSIBLE GASTROENTERITIS: SODIUM TRANSPORT AND THE INTESTINAL EPITHELIUM DURING THE COURSE OF VIRAL ENTERITIS. (Eng.) Kerzner, B.; Kelly, M. H.; Gall, D. G.; Butler, D. G Hamilton, J. R. (Hosp. Sick Children, 555 University Ave., Toronto, Ontario M5G 1X8, Canada). *Gastroente ology* 72(3):457-461; 1977.

Sodium transport, mucosal structure, and epithelial zymes were studied in the jejunum of piglets killed 25, 40, 72, or 144 hr after infection with a standa dose of transmissible gastroenteritis virus, to obtain information on the stage of epithelial differentiation. Glucose-stimulated Na transport measured in short-circuited jejunal epithelium and suspensio of villous enterocytes became progressively more abnormal during the first 40 hr, but recovered completely by 144 hr. As Na transport deteriorated, jejunal mucosal villi shortened and crypts deepened. Cells isolated from the villi became more crypt-lik in their enzyme profile, with high levels of thymidine kinase and low levels of sucrase activity 40 h after infection. At 40 hr, when diarrhea is severe, little if any virus was found in the epithelium. These data suggest that the relatively undifferentiated crypt type enterocytes on the villi constitute an important determinant of altered Na transport an diarrhea in this invasive viral enteritis.

2963 EFFECT OF INTESTINAL DISTENTION ON LEVELS OF CYCLIC AMP AND FLUID SECRETION. (Eng. Turjman, N.; Yardley, J. H.; Hendrix, T. R.; Gotter G. S. (Johns Hopkins Univ. Sch. Medicine, 725 N. Wolfe St., Baltimore, MD 21205). *Johns Hopkins Me J.* 140(3):97-99; 1977.

Studies were carried out in loops of rabbit jejunum to determine whether an increase in intestinal cyclic AMP accompanies increased intestinal secretion induced by intestinal distension. Increased secretion was seen only when the *in vivo* loops were fully distended, when peristalsis was obliterated. Cyclic AMP levels were not significantly changed, compared with control loops. Histologic examination of the distended loops showed no significant changes from normal. The data indicate that the secretion in response to distension can occur in the absence of morphological alteration and is not mediated by the elevation of intestinal cyclic AMP.

2964 STIMULATION OF ENZYME, PROTEIN, AND DNA OUTPUT FROM A JEJUNAL FISTULA IN THE RAT.

(Eng.) Schneeman, B. O.; Nasset, E. S. (Children's Hosp. Medical Center Northern California, Fifty-First and Grove St., Oakland, CA 94609). *Proc. Soc. Exp. Biol. Med.* 154(2):250-253; 1977.

A new technique for preparing intestinal fistulae in rats is presented. Perfusion of the fistula is facilitated by inserting small-diameter tubing into the closed orad end of the fistula. The distal end protrudes 0.5 cm through the belly wall for quantitative collection of perfusate or secretion. Continuity of the gut is reestablished by a side-to-side anastomosis. Analysis of the mucosa from the fistula and from the intact intestine demonstrated that the mucosae were comparable during the week the animals were used for perfusion experiments. The duodenal infusion of raw egg white stimulated the output of protein, DNA, peptidase, and alkaline phosphatase activity in the jejunal fistula perfusate. The jejunal fistula described allows easy perfusion of the lumen and quantitative collection of the perfusate.

2965 EFFECT OF 50% DISTAL SMALL BOWEL RESECTION ON GASTRIC EMPTYING IN RHESUS MONKEYS.

(Eng.) Hall, A. W.; Moossa, A. R.; Skinner, D. B. (Pritzker Sch. Medicine, Univ. Chicago, 950 East 59th St., Chicago, IL 60637). *Ann. Surg.* 185(2):214-218; 1977.

The effect of 50% bowel resection on gastric emptying was studied in eight male Rhesus monkeys. Gastric evacuation was characterized by a modified double sampling test meal, after which 50% distal small bowel resection was performed. Gastric emptying was again studied at 6 weeks and 6 months. The rate constant fell from -0.00289 ± 0.000467 to -0.00232 ± 0.00106 during the early phase, but rose to -0.00308 ± 0.00186 by 6 months, neither value being statistically different from the preoperative values. The time taken for the intragastric contents to fall to 10 ml ($T_{\frac{1}{2}}$=half life of a meal in the stomach) rose from 125.2 ± 19.2 min to 367 ± 173.4 min by 6 weeks and to 380.9 ± 161.6 min by the end of the experiments. Corresponding values for $T_{\frac{1}{2}}$ were: control period 425.8 ± 63.2 min, early phase 1,223 ± 589 min, and late phase 1,245.9 ± 529.6 min. None of these changes were statistically significant. Alterations in emptying time within each animal were consistent at the two postoperative phases. Although the two animals showing acceleration of evacuation were those with least change in secretion, compensation for the observed increase in output of gastric juice did not alter the results. The results show no specific effect of 50% enterectomy on gastric emptying.

2966 CONSEQUENCES OF PARTIAL AND SUBTOTAL COLECTOMY IN THE RAT.

(Eng.) Masesa, P. C.; Forrester, J. M. (Univ. Dar es Salaam, P.O. Box 20693, Dar es Salaam, Tanzania). *Gut* 18(1):37-44; 1977.

The effects of partial and subtotal colectomy in male Wistar rats were investigated by comparing rats subjected to right hemicolectomy, left hemicolectomy, subtotal colectomy, or colon bypass with control "operated" and unoperated "normal" rats. Hemicolectomy did not alter food intake, and body weight began to increase normally 1 week after the operation. Right hemicolectomy did result in a 37% increase in fecal weight. Propulsion activity from the small intestine was definitely poorer after right hemicolectomy, and significant compensatory growth was observed in the distal colon and small intestine. Three months after operation, growth in the small intestine was predominantly mucosal, and enterocyte density increased throughout, while villous height increased in the proximal segment ($p<0.05$). Similar changes were not observed after left hemicolectomy. Subtotal colectomy and colon bypass resulted in a 30-40% increase in food consumption and a 60% increase in fecal dry weight (at 3 months) over controls. Poor absorption was indicated by large amounts of energy excreted, despite higher food intake. Proper absorption may have been partially disrupted by a decrease in the stomach-to-anus transit time. Increased villous height, as well as significant growth of the mucosae in the upper two thirds, and of the seromucosal coat in the lower third of the small intestine, as also observed after subtotal colectomy and colon bypass. Pair feeding with control rats eliminated the increase in food intake, but not the increase in weight of the small intestine. Decreased coprophagy and absorption may have been partially responsible for the increase in food intake after subtotal colectomy. However, increased weight of the small intestine observed after both right hemicolectomy and subtotal colectomy was not always concurrent with increased food intake, and did not even require actual colectomy.

GENERAL

2982 PREDICTION OF INTESTINAL VIABILITY BY INTRA-ARTERIAL DYE INJECTION: A SIMPLE TEST. (Eng.) Papachristou, D.; Fortner, J. G. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021). *Am. J. Surg.* 132(5):572-574; 1976.

Preliminary data on a simple test for intestinal vi bility by intra-arterial dye injection is presented In adult Fischer rats, a 4-cm segment of terminal ileum was ligated for less than 2 hr, for 2-4 hr, o for 5-8 hr. At revascularization, the viability wa predicted in three different ways: on clinical

ounds (i.e., return of motility, color, pulsations),
measuring the temperature difference between the
timesenteric border of the loop and the adjacent
althy intestine (using an electronic thermometer
obe) to predict reactive hyperemia (if the loop
mperature was at least 1 C higher than that of the
rmal bowel), and by the dye injection method. In
e latter technique, 1-2 ml of a 0.4% saline solution
trypan blue is injected into the superior mesen-
ric artery. The dye stains normal intestine and
able parts of the previously ischemic loop, but
t nonviable areas. The accuracy of the three me-
ods in viability prediction was 36%, 69%, and 84%,
sp., for the three techniques. Two patterns of
chemia were detected by the trypan blue test. With
e, the whole ischemic loop or large areas of bowel
mained unstained. In the second type, only small
ots of the loop remained unstained; perforations
bsequently occurred at exactly the same positions.
e intra-arterial dye injection technique is a simple,
sy, and inexpensive way to accurately predict the
ability of ischemic intestine, and it appears to be
inically useful.

33 DYNAMICS OF THE ENTEROHEPATIC CIRCULATION
OF THE GLYCINE CONJUGATES OF CHOLIC, CHENO-
OXYCHOLIC, DEOXYCHOLIC, AND SULFOLITHOCHOLIC ACID
MAN. (Eng.) Hepner, G. W.; Demers, L. M. (Har-
r General Hosp., 1000 West Carson St., Torrance,
90509). *Gastroenterology* 72(3):499-501; 1977.

e kinetics of the enterohepatic circulation of con-
gated bile acids were studied in eight healthy sub-
cts, using sensitive and specific radioimmunoassays.
nous blood samples were collected over a 32-hr per-
d, during which time the subjects ate three meals
heese sandwich and milk). Serum levels of cholyl-
ycine and chenodeoxycholylglycine rose after each
al, and reached their maximum level within 30-60 min.
second chenodeoxycholylglycine peak occurred 2-3 hr
ter the first two meals in all subjects; a second
ak was also seen for cholylyglycine in three subjects.
rum deoxycholylglycine levels also rose postprandial-
; the peak level generally occurred 30 min later than
at of cholylglycine. Serum sulfolithocholylglycine
vels did not alter significantly after meals. The
ta indicate that the dynamics of the enterohepatic
rculation of individual serum bile acids differ both
antitatively and qualitatively.

34 PHARMACOKINETICS OF MOTILIN IN MAN. (Eng.)
Mitznegg, P.; Bloom, S. R.; Domschke, W.;
schke, S.; Wuensch, E.; Demling, L. (Dept.
armacology, Univ. Erlangen-Nuremberg, Universitats-
rasse 22, D-852 Erlangen, W. Germany). *Gastro-
terology* 72(3):413-416; 1977.

e physiologic role of motilin was studied in man.
nthetic 13-norleucine-motilin (0.6 and 2.4 pmol/
/min over 60 min) was infused into six healthy
lunteers, and plasma motilin was measured by radio-
munoassay. During the infusions, mean plasma
vels of 124.8 ± 14.8 and 360 ± 19.6 pmol/l,
sp., were achieved for the 0.6 and 2.4 pmol/kg/
n-doses. Disappearance half-time on stopping the
infusion was 4.36 min. The apparent volume of distribution was calculated to be 49.4 ± 3.3 ml/kg, and the metabolic clearance rate was 7.8 ± 0.5 ml/kg/min. To measure the decay of endogenous motilin, somatostatin was used in the same six subjects. A bolus of 100 μg and a subsequent 15-min infusion of 15 μg/min of somatostatin suppressed the fasting motilin level by 50%. The disappearance half-time was 4.56 min. It is concluded that both synthetic and endogenous motilin are eliminated by first order kinetics with very similar half-times. The data also suggest that the previously reported motilin infusions at these dose levels gave plasma concentrations within the physiological range and that the effects noted may thus have reflected the physiological actions of motilin.

2985 ANTIBODY-DEPENDENT CELL-MEDIATED CYTOTOXICITY. COMPARATIVE ABILITY OF MURINE PEYER'S PATCH AND SPLEEN CELLS TO LYSE LIPOPOLYSACCHARIDE-COATED AND UNCOATED ERYTHROCYTES. (Eng.) Kagnoff, M. F.; Campbell, S. (Dept. Medicine, Univ. California, San Diego, La Jolla, CA 92037). *Gastroenterology* 70(3):341-346; 1976.

The ability of Peyer's patch cells and of spleen cells to kill target cells by antibody-dependent cell-mediated cytotoxicity (ADCC) was assessed. Chicken RBC were coated with bacterial lipopolysaccharides (LPS) and labeled with ^{51}Cr. Anti-serum was produced against these cells, as well as against uncoated, labeled cells. Normal spleen cells from unimmunized mice specifically lysed both type of cells when the appropriate anti-serum was present. However, Peyer's patch cells did not kill either target cell in the presence of their anti-sera. Peyer's patches in mice appear to be deficient in the effector cell type(s) required to kill antibody-coated RBC target cells by an ADCC mechanism, as well as the macrophage-like accessory adherent cell type(s) required for the induction of humoral antibody synthesis and cell-mediated cytotoxic allograft reactions *in vitro*. The authors suggest that models of ADCC may be useful when determining mechanisms of immune tissue injury in certain intestinal diseases.

2986 FASTING AND REFEEDING: CELL KINETIC RESPONSE OF JEJUNUM, ILEUM AND COLON. (Eng.) Hagemann, R. F.; Stragand, J. J. (Allegheny General Hosp., 320 East North Ave., Pittsburgh, PA 15212). *Cell Tissue Kinet.* 10(1):3-14; 1977.

Adult female Ha/ICR mice were fasted and then fed their normal diet of lab chow or a low residue diet. At various intervals during fasting and refeeding, mice were sacrificed 30 min after injecting 50 μCi of tritiated thymidine. Colonic, ileal, and jejunal tissue samples were checked for cell proliferation by counting the disintegrations/min/mg of wet tissue, the number of labeled nuclei per single isolated crypt, and the number of mitotic figures per crypt. During the fasting time, the ileal and jejunal crypt proliferative compartments and the total crypt cellularity decreased significantly, while the G_1 and S phases of the cell cycle were lengthened. After refeeding, the proliferation levels gradually returned to normal values, with a slight overshoot in S-phase cellularity. Fasting had no effect on the colonic proliferative compartment or the cellularity, but the G_1 phase doubled. Refeeding caused a prompt increase in proliferative indices, with peak S cellularity levels exceeding the fasting levels four times and twice the control values. These changes in cellularity caused by dietary manipulation may provide a useful tool for further investigations of colonic carcinogenesis.

2987 THE IMPORTANCE OF Clostridia IN EXPERIMENTAL INTESTINAL STRANGULATION.

(Eng.) Yale, C. E.; Balish, E. (Univ. Wisconsin Medical Sch., Madison, WI). *Gastroenterology* 71(5):793-796; 1976.

Hemorrhagic and ischemic strangulation of closed intestinal segments was studied in germ-free rats individually monocontaminated with one of eight separate species of *Clostridia*. The *Clostridia*, ranked in the order of decreasing lethality were: *Clostridium perfringens* type A, *C. septicum, C. histolyticum, C. haemolyticum, C. bifermentans, C. sporogenes, C. tertium, and C. novyi* type A. *C. histolyticum* and *C. septicum* killed all animals within 26-70 hr after operation, whereas *C. bifermentans, C. novyi, C. perfringens,* and *C. sporogenes* were relatively nonlethal. The individual species of *Clostridium* produced the same pattern of survival, regardless of whether the test segment was hemorrhagically or ischemically strangulated. In the presence of dead tissue, *C. perfringens* was the most potent of the *Clostridia*, killing all animals within 7-11 hr after operation, whereas *C. novyi* continued to be inocuous. All species were readily established in the gastrointestinal tracts of the nonoperated germ-free rat. The *Clostridia* appear to be one of the most potentially lethal groups of organisms commonly found in the intestinal tract of humans and animals.

2988 SUPPRESSION OF GIARDIASIS DURING THE INTESTINAL PHASE OF TRICHINOSIS IN THE MOUSE.

(Eng.) Roberts-Thomson, I. C.; Grove, D. I.; Stevens, D. P.; Warren, K. S. (Univ. Hosp., Cleveland, OH 44106). *Gut* 17(12):953-958; 1976.

The interaction of the intestinal phases of *Giardia muris* and *Trichinella spiralis* was investigated in Swiss albino mice in an effort to clarify nonimmunological host defense mechanisms. Intraesophageal inoculation of *G. muris* cysts 7 days before, or 7 days after, similar inoculation of *T. spiralis* larvae resulted in significant reduction in the numbers of *Giardia* trophozoites in the small bowel and *Giardia* cysts in stools. This effect was not observed when *G. muris* cysts were administered after resolution of the intestinal phase of trichinosis. Giardiasis had no effect on trichinosis, as assessed by numbers of adult worms in the small bowel and larvae in skeletal muscles. The intestinal phase of trichinosis was associated with increased numbers of inflammatory cells in the lamina propria of the small bowel, a significant increase in Paneth cells in crypts, and a marked reduction in the villus to crypt ratio of jejunum. These observations suggest that the intestinal phase of trichinosis induced environmental changes in the small bowel, perhaps related to inflammation, which resulted in suppression of proliferation of *Giardia* trophozoites.

2989 EXPERIMENTAL PROTEIN-LOSING GASTROENTEROPATHY: ROLE OF TISSUE PLASMINOGEN ACTIVATOR.

(Eng.) Kondo, M.; Nakanishi, K.; Bamba, T.; Hosokawa, K.; Masuda, M. (Kyoto Prefectural Univ. Medicine, Kyoto, Japan). *Gastroenterology* 71(4):631-634; 1976.

To add further support to the previous clinical observation that tissue fibrinolytic activity in the digestive mucosa of patients with protein-losin gastroenteropathy is increased, fibrinolytic activit was studied in male Wistar rats with different type of experimental protein-losing gastroenteropathies. This condition was produced by x-irradiation, 5-fluorouracil treatment (25 mg/kg, i.p.), or ligatio of the thoracic duct. The first two models showed an increase of fibrinolytic activity and of ^{131}I-polyvinylpyrrolidone (^{131}I-PVP) excretion. Irradiated rats excreted 8.9% of the administered dose of ^{131}I-PVP in 5 days, but excreted only 4.3% of the dose when treated with *trans*-4-aminomethyl cyclohexane carboxylic acid (*trans*-AMCHA); this indicates that antiplasmin was effective in preventing enteric protein loss after irradiation. Nonirradiated rats receiving saline or *trans*-AMCHA excreted 3.9% and 3.7%, resp., of the injected ^{131}I-PVP. The mean 5-day ^{131}I-PVP excretion of 5-fluorouracil-treated rats was 13.9%, whereas that of controls was 4.2%; *trans*-AMCHA treatment reduced this excretion to 6.9%. Normal fibrinolysi was seen in the thoracic duct-ligated animals, and the administration of *trans*-AMCHA did not prevent ^{131}I-PVP fecal excretion. The results support the hypothesis that tissue fibrinolysis in the digesti mucosa plays an important role in the pathogenesis of protein-losing gastroenteropathy associated wit diseases of the mucosa.

2990 EVOLUTION OF LESIONS IN INTESTINAL ISCHE

(Eng.) Ming, S. C.; Bonakdarpour, A. (Temple Univ. Health Sciences Center, 3400 N. Broa St., Philadelphia, PA 19140). *Arch. Pathol. Lab. Med.* 101(1):40-43; 1977.

Small intestinal ischemia was produced in dogs by ligation and division of a branch of the superior mesenteric artery, and the development of lesions was studied. The bowel was examined on or before the 60th day after the induction of ischemia. The bowel lesions included patchy mucosal necrosis, ul ceration, and stenosis. Mucosal congestion was present in all seven dogs killed up to 22 days aft operation. Ulceration was accompanied by severe submucosal inflammation in a uniform pattern. Mu-

osal regeneration occurred from either the remnants
f glands in the ulcer base or the mucosa at the
lcer margin. The regenerated mucosa was lined
ith irregular glands without villous formation.
arly villous formation was seen 22 days after oper-
tion. With healing, inflammation slowly regressed,
nd the granulation tissue became evident. By about
ay 30 after operation, well developed villi that
ere shorter and more blunt than normal were seen
n regenerated mucosa. The underlying submucosa was
ibrosed; the fibrous tissue was vascular in some
reas and collagenous in others. Focal disruption
f the muscularis mucosa and loss of ganglion cells
ere common, although the muscularis propria remained
argely intact. The malabsorption and slow return
f bowel function in patients with intestinal is-
hemia is explained by the incomplete development of
he villi in the regenerated mucosa.

991 EFFECT OF PENTAGASTRIN ON BLOOD FLOW DISTRIBUTION IN THE STOMACH OF CATS WITH GAS- RIC ULCER.

(Eng.) Skarstein, A.; Svanes, K.;
reide, O.; Varhaug, J. E. (Dept. General Surgery,
niv. Bergen, Haukeland Hosp., Bergen, Norway).
cand. J. Gastroenterol. 12(1):71-76; 1977.

esthetized cats with week-old-induced gastric
lcers and normal controls were given pentagastrin
.15 or 0.3 µg/kg/min, i.v.) for 20 min, and labeled
icrospheres were used to measure the blood flow in
astric tissues. The blood flow in the muscularis
as not influenced by pentagastrin in any of the
nimals. Normal cats showed an increase in mucosal
lood flow to all parts of the stomach, except the an-
rum, after pentagastrin administration, while cats
ith ulcers had no significant change in the mucosal
lood flow. These findings indicate that pentagastrin
ay act through local release of histamine. Cats with
lcers may not respond to gastrin because of vasal
onstriction caused by H^+ backflow in the injured
ucosa. The release of prostaglandin E_1 in the in-
lamed area may also counteract the effect of penta-
astrin.

92 SUDDEN POTENTIAL DROP IN BULLFROG GASTRIC MUCOSA.

(Eng.) Kidder, G. W. III; Mont-
omery, C. W. (Univ. Maryland Sch. Dentistry, Balti-
ore, MD 21201). *Am. J. Physiol.* 230(1):61-66; 1976.

e relationship between voltage and transepithelial
ssue resistance was used to measure conditions
ecessary for the sudden potential drop (SPD) occur-
ing under anoxia in 10% CO_2 in bullfrog (*Rana cates-*
iana) gastric mucosa. An equivalent circuit model
at helps to explain many of the properties of SPD
presented. The SPD and corresponding drop in re-
istance occurred regularly at 10% CO_2 per 25 mM HCO_3
H 7.1), but never at 5% CO_2 per 25 mM HCO_3 (pH 7.4);
seemed to control this effect. The resistance drop
crossing the critical clamp voltage was 171 ± 21
ms/cm^2; Rm dropped to 85% of its "high voltage" at
is time ($p<0.01$). Increasing the clamp voltage
ck to 120 mV resulted in a rise of 490 ± 74 ohms/cm^2.
resistant drop could not be produced by voltage
lamping under aerobic conditions. SPD did not occur
when Cl^- was removed from the solution. Cl^- was apparently necessary for the SPD response, even when the voltages were maintained at normal values by clamping. While the pH dependence of the SPD could not consistently be demonstrated in phosphate-buffered solutions, the trend favored lower pH values. Since neither Na^+ or K^+ gave a significant voltage change during post-SPD anoxia, the postulated shunt pathway does not seem to involve selective permeability for either ion. The proposed model does not predict the observed rise in potential difference (PD), which normally accompanies the first few minutes of anoxia, nor does it predict the PD reversal, which occurs with this response.

2993 AMYLASE CLEARANCE IN ACUTE PANCREATITIS: EXPERIMENTAL STUDY IN THE GUINEA PIG.

(Eng.) Orda, R.; Orda, S.; Wiznitzer, T.; Bawnik, J. B. (2 Ashbourne Mansions, Ashbourne Ave., London N.W.11., England). *J. Surg. Res.* 21(6):457-461; 1976.

Amylase clearance was studied in guinea pigs with experimental acute pancreatitis, duodenal perforation, or intestinal infarction. Pancreatitis was induced by the interstitial injection into the pancreatic parenchyma of sodium taurocholate (1 ml). The mean serum amylase levels were 1,044.0 ± 289.6, 1.553.1 ± 671.9, 1,472.0 ± 283.0, and 1,335.1 ± 287.1 Somogyi U in normal controls, pancreatitis, duodenal perforation, and intestinal infarction, resp. These values were not significantly different. The amylase-creatinine clearance ratio was significantly increased ($p<0.001$) in the animals with acute pancreatitis in comparison with the other groups; the mean values were 1.8 ± 0.7%, 4.5 ± 1.6%, 2.0 ± 0.7%, and 1.8 ± 0.7% for the normal controls, acute pancreatitis, duodenal perforation, and intestinal infarction groups, resp. The results illustrate the value of the amylase-creatinine clearance determination in the differential diagnosis of acute pancreatitis.

DIAGNOSTIC PROCEDURES

3039 ROENTGENOLOGIC FEATURES OF CAUSTIC CHANGES IN THE UPPER INTESTINAL TRACT. (Ger.) Frommhold, H.; Rohner, H. G.; Koischwitz, D.; Kuhr, J. (Radiologische Universitatsklinik, 5300 Bonn-Venusberg, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 125(6):514-520; 1976.

Functions of radiology and endoscopy in determining the form and extent of caustic damage in early and late stages of upper gastrointestinal tract disease in humans are compared. The importance of radiology in demonstrating perforations, controlling drug and dilatation therapy, and showing the presurgical condition is outlined. Endoscopy, on the other hand, should be utilized in the differentiation of early caustic damage when the x-ray is negative, in the control of the disease course during therapy, and in the clarification of atypical late changes to exclude malignant degeneration.

3040 DIAGNOSTIC VALUE OF BIOPSY, GUIDED LAVAGE, AND BRUSH CYTOLOGY IN ESOPHAGOGASTROSCOPY. (Eng.) Halter, F.; Witzel, L.; Gretillat, P. A.; Scheurer, U.; Keller, M. (Inselspital, 3010 Berne, Switzerland). *Am. J. Dig. Dis.* 22(2):129-131; 1977.

In a prospective study, 96 patients with esophageal and gastric lesions were investigated by multiple endoscopic biopsy, brush cytology, and guided lavage cytology, to evaluate the diagnostic accuracy of each of these methods. Fifty malignant and 46 benign lesions were found. The final diagnosis was proven by operation or autopsy in 53 patients, by multiple endoscopic follow-up in 31, and by clinical control in 8. No follow-up was possible in four patients. The malignant lesions were diagnosed by multiple biopsy in 86.0%, by brush cytology in 84.0%, and by lavage cytology in 50.0%. The diagnostic yield of lavage cytology was significantly lower ($p<0.01$) than the other methods. A combination of multiple biopsy and brush cytology is the most valuable aid in endoscopic diagnosis of esophageal and gastric malignancy, with a diagnostic accuracy of 96%.

3041 DIAGNOSTIC METHODS IN THE BULBUS DUODENI. AGREEMENT AND DISAGREEMENT BETWEEN ENDOSCOPIC, ROENTGENOLOGICAL AND HISTOLOGICAL EXAMINATIONS. (Ger.) Dette, G. A.; Fruhmorgen, P.; Classen, M.; Bauerle, H.; Kissling, U.; Demling, L. (Institut fur Physiologische Chemie II der Universitat Marburg, Deutschhausstr. 1-2, D-3550 Marburg, W. Germany). *Munch. Med. Wochenschr.* 119(5):139-142; 1977.

Of 1,012 patients examined by endoscopy with biopsy and upper gastrointestinal series, pathological findings were detected in 346 patients (268 men, 78 women). Nonspecific upper gastric and ulcer symptoms and hematemesis and bloody stool were the most frequently encountered complaints. Endoscopic and roentgenological findings totally agreed in 210 cases (64.6%), but they showed disagreement in 115 patients (35.4%). The most controversial findings were in cases of cicatricial ulcer/duodenal ulcer or *vice versa*. False-negative ulcer findings were noted in 20.8%, and false-positives in 28%. The findings were questionable in 26%. Bulbus symptoms occurred about 10 yr later in women than in men. A carcinoma was diagnosed falsely by roentgenologic findings, but none of five endoscopically and histologically confirmed cases of malignancies were overlooked.

3042 PROCTOSIGMOIDOSCOPY AND RECTAL BIOPSY IN INFANTS AND CHILDREN. (Eng.) Vanderhoof, J. A.; Ament, M. E. (Univ. California Los Angeles Sch. Medicine, Los Angeles, CA 90024). *J. Pediatr.* 89(6):911-915; 1976.

The records of patients aged 2 days to 20 yr (median age, 2 yr) who underwent proctosigmoidoscopy and/or rectal biopsy over a 27-month period were reviewed to determine the efficacy and safety of these procedures in pediatric patients. One hundred twenty-one patients underwent proctosigmoidoscopy; 91 of these also had rectal biopsies. Thirty-four patients had rectal biopsy alone. The depth of examination was 10-15 cm in most patients older than 10 yr, and this was also true in many small infants. The four most common indications for proctosigmoidoscopy included chronic diarrhea (42), rectal bleeding (23), bloody diarrhea (20), and abdominal pain (12). Proctosigmoidoscopy showed normal results in 10 of the 12 patients with abdominal pain. The findings were abnormal in 17, 17, and 19 of the patients with chronic diarrhea, rectal bleeding, and bloody diarrhea, resp. Ulcerative colitis was the most common diagnosis (24 patients) in patients with rectal bleeding, with or without diarrhea. Induced friability was the most frequently described mucosal abnormality (58 patients) and occurred in the absence of spontaneous friability in 18 patients, indicating that multiple mucosal wipe tests are necessary to exclude colitis by proctosigmoidoscopy. Anal fissures were found in only 4 of 23 patients with rectal bleeding. Morbidity was 0% with proctosigmoidoscopy and 0.34% with rectal suction biopsy. These studies demonstrate the safety of performing both proctosigmoidoscopy and rectal biopsy, even in very small infants.

3043 VISUALIZATION OF THE LATERAL EDGE OF THE LIVER IN ASCITES. (Eng.) Love, L.; Demos, T. C.; Reynes, C. I.; Williams, V.; Shkolnik, A.; Gandhi, V.; Zerofos, N. (Loyola Univ. Medical Center, 2160 S. First Ave., Maywood, IL 60153). *Radiology* 122(3):619-622; 1977.

Thirty-five cases of ascites were studied to determine whether medial displacement of the lateral edge of the liver is pathognomonic of ascites. Techniques included plain radiographs, total-body opacification, tomography, radio-nuclide imaging, peritoneography, and/or ultrasonography. The lateral margin of the liver was demonstrated on the preliminary radiograph unequivocally in 16 cases and questionably in 3. In the remaining 16 cases, medial displacement was visualized by total-body opacification, peritoneography, radionuclide imaging, or ultrasonography. Separation of the liver and kidney was seen on ultrasonograms in every case; visualization was increased by the addition of increments of fluid in patients undergoing peritoneal dialysis. Since the liver is surrounded by fluid, an interface between it and the extraperitoneal fat cannot account for the displacement seen on plain radiographs; rather, this is the result of a difference in density between liver and fluid.

3044 HEPATIC DUCT DIVERTICULUM SIMULATING A CHOLEDOCHAL CYST.

(Eng.) Schey, W. L.; Pinsky, S. M.; Lipschutz, H. S.; Dragomer, A. S. (Michael Reese Medical Center, 29th St. and Ellis Ave., Chicago, Il 60616). *Am. J. Roentgenol.* 128(2): 318-320; 1977.

The case of a 12-yr-old boy with a hepatic duct diverticulum simulating a choledochal cyst is presented. The patient presented with a right upper quadrant mass, hepatosplenomegaly, fatigue, and abdominal pain. No jaundice was present. Radiographically, the findings of a displaced gallbladder and duodenum were consistent with a choledochal cyst. In addition, the alkaline phosphatase level was high (123 Bodansky U). The presence of esophageal varices, the absence of jaundice, and the absence of infection made the diagnosis of choledochal cyst less likely. Hepatic scanning with ^{67}Ga citrate yielded findings similar to those of a ^{99m}Tc sulphur colloid study; a noninflammatory, nonneoplastic, "cystic" impression or intrahepatic cystic mass was suggested by both examinations. The correct diagnosis was suggested preoperatively, primarily because of the location of the "mass," the high alkaline phosphatase value, and the absence of jaundice.

3045 GRAY SCALE ULTRASOUND AND ISOTOPE SCANNING: COMPLEMENTARY TECHNIQUES FOR IMAGING THE LIVER.

(Eng.) Taylor, K. J. W.; Sullivan, D.; Rosenfield, A. T.; Gottschalk, A. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Am. J. Roentgenol.* 128(2):277-281; 1977.

Five cases are presented in which liver examination by gray scale ultrasound allowed a definitive diagnosis of an abnormality observed on the isotope scan or resolved the cause of an equivocal isotope scan into a definite abnormality or an anatomic variation. In the first patient, a 52-yr-old woman who had undergone a left mastectomy for carcinoma, a ^{99m}Tc sulfur colloid scan suggested metastatic disease in the right liver lobe. Gray scale ultrasound examination demonstrated a cystic lesion with a regular, well defined, margin and no evidence of internal echoes, and a repeat echo examination 6 months later showed no change in size or shape of the cyst. In a second patient with a positive ^{99m}Tc scan, ultrasound revealed a large abnormality consisting of a thick rim of high-level echoes with low central ones, suggesting an abscess, which was confirmed surgically. The liver scan in the third patient, a 65-yr-old woman in whom a cystadenocarcinoma of the ovary had been removed, demonstrated a questionable defect at the porta hepatis, interpreted as an anatomic variant. Ultrasound showed an irregular mass, returning low-level echoes, invadin the liver, and the patient subsequently succumbed with liver metastasis. In the fourth patient, the isotope liver scan suggested an enlarged renal impression or a intrahepatic lesion; ultrasound showed an irregular mass situated above the right kidney and extending deeply into the right liver lobe, a characteristic of metastatic liver involvement (in this case from a breast malignancy). The liver scan in a 29-yr-old man treated for testicular teratoma suggested a normal gallbladder fossa; ultrasound examination showed three 2-cm tumors, partially necrotic. The findings were confimred at autopsy. Ultrasound is now an important complementary technique to radioisotope scanning.

3046 ULTRASONIC AND RADIOGRAPHIC CHOLECYSTOGRAPHY.

(Eng.) Bartrum, R. J., Jr.; Crow, H. C.; Foote, S. R. (Dartmouth Medical Sch., Hanover, NH 03755). *N. Engl. J. Med.* 296(10):538-541; 1977.

To define the relative merits of radiographic and ultrasonic cholecystography, 208 patients with possible cholelithiasis were studied. The patients underwent both procedures, and the results were interpreted in blind fashion. Two hundred patients had satisfactory confirmation of their diagnosis, by either a well visualized radiographic cholecystogram or operation or both. The overall accuracy of the ultrasonic examination was 93%, with a false-negative rate of 11% and an indeterminate rate of 4%. The indeterminate rate was 24% for the single-dose p.o. cholecystogram and 8% for the double-dose cholecystogram. Both ultrasonic cholecystography and radiographic cholecystography are useful in the detection of gallstones. The findings support the use of single-dose p.o. cholecystography as the routine first examination. If the gallbladder is not satisfactorily visualized, ultrasonic cholecystography can be performed immediately. In an emergency or for patients with a suspected pregnancy, ultrasonic cholecystography is available as the initial examination.

3047 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY WITH SELECTIVE CATHETERIZATION OF THE COMMON BILE DUCT.

(Eng.) Burcharth, F.; Nielbo, N. (Gentofte Hosp., Univ. Copenhagen, DK-2900 Hellerup, Copenhagen, Denmark). *Am. J. Roentgenol.* 127(3):409-412; 1976.

Percutaneous transhepatic cholangiography with selective catheterization of the common bile duct was carried out in 86 patients with jaundice in whom the diagnosis could not be established by conventional means. The catheter was introduced through the mid-axillary line at the level of the 12th thoracic vertebra. Where possible, the bile duct was entered o the right side of the hilus, allowing the catheter to be conducted by the guidewire technique to the common duct or close to an obstruction. If successful puncture of a bile duct did not occur at the first attempt, the direction of the cannula was altered without completely retracting it from the liver. In cases of biliary obstruction, the catheter was left in place for external bile drainage. The biliary tree was visualized in 74 patients; normal bile ducts were seen in 14. In all 60 patients with obstruction, the biliary tree and the obstruction were disclosed by the procedure, and the diagnosis was verified at surgery and/or autopsy. Complications (including bile lead and bleeding) occurred in four patients, but were not exclusively due to the procedure. The incidence of complications may be limited if the technique is meticulously followed.

3048 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY USING THE "CHIBA" NEEDLE--80 CASES.

(Eng.) Jain, S.; Long, R. G.; Scott, J.; Dick, R.; Sherlock, S. (Royal Free Hosp., Hampstead, London NW3 2QG, England). *Br. J. Radiol.* 50(591):175-180; 1977.

The Chiba needle was used for percutaneous transhepatic cholangiography in 80 patients with cholestatic jaundice in whom p.o. or i.v. cholangiography was impossible or in whom these procedures had proved unsatisfactory. The bile ducts were visualized radiographically in 80% of the patients. The success rate was 94.4% in the 54 patients with dilated bile ducts due to an extrahepatic biliary obstruction, and 50% in the 20 patients with undilated ducts. Four patients developed ascending cholangitis with septicemia on the same day as the procedure; early surgery after visualization of obstructed bile ducts is recommended. The technique was successful in three of five patients with sclerosing cholangitis. Percutaneous cholangiography with a Chiba needle is a convenient method of opacifying the biliary system in patients with severe large bile duct obstruction.

3049 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE MANAGEMENT OF PANCREATIC AND BILIARY DISEASE.

(Eng.) Mullens, J. E.; Laufer, I. (McMaster Univ. Medical Centre, 1200 Main St. W., Hamilton, Ontario L8S 4J9, Canada). *Can. J. Surg.* 19(5):405-409; 1976.

Endoscopic retrograde cholangiopancreatography (ERCP) in the management and diagnosis of pancreatic and biliary disease is reviewed. The indications for ERCP include obstructive jaundice, chronic or recurrent pancreatitis, upper abdominal pain of obscure origin, and suspected pancreatic pseudocyst or upper abdominal mass. Contraindications include acute pancreatitis and some cases of cholangitis. Complications of ERCP include acute pancreatitis, cholangitis, and transmission of infectious disease. To prevent pancreatitis and cholangitis, the endoscopist must avoid overfilling the pancreatic and bile ducts. Endoscopic sphincterotomy of the sphincter of Oddi and the extraction of stones from the common bile duct are extensions of this procedure already in use. Cannulation of the bile ducts and pancreatic ducts in tests of secretion and cytology will become increasingly common applications of the technique.

3050 COMPARATIVE VALUE OF FOUR METHODS OF INVESTIGATING THE PANCREAS.

(Eng.) Wood, R. A. B.; Moossa, A. R.; Blackstone, M. O.; Bowie, J.; Collins, P.; Lu, C. T. (Pritzker Sch. Medicine, 950 East 59th St., Chicago, IL 60637). *Surgery* 80(4):518-522; 1976.

The comparative value of ultrasonography, radionuclide scanning, selective arteriography, and endoscopic retrograde cholangiopancreatography (ERCP) in the diagnosis of pancreatic cancer was studied in 89 patients. Fifty-eight patients underwent laparotomy, and 36 were found to have periampullary cancer; 7 had other malignant tumors within the abdomen, and 9 had pancreatitis on biopsy. Five patients had other benign diseases, and there was one negative laparotomy. Thirty-one patients who did not have laparotomy have shown no evidence of cancer at 1-yr follow-up. Among the patients with periampullary cancer, a correct-positive diagnosis was made in 19 of 25 examined with ultrasound, in 10 of 18 examined with radionuclide scanning, in 12 of 18 examined by arteriography, and in 18 of 21 examined with ERCP. Among the nine patients with pancreatitis, a correct-positive diagnosis was made in 5/9, 3/8, 3/9, and 5/7 patients using the respective procedures. The overall accuracy of ERCP was 88%, while that of ultrasound, pancreatic scan, and arteriography was 72%, 64%, and 64%, resp. Since ultrasonography involves no risks to the patient and is the most tolerable procedure, the authors suggest that it should be the first line of investigation in patients suspected of having pancreatic disease. ERCP, having the highest accuracy, should be the most advanced procedure for providing a definitive diagnosis.

3051 LYMPHOCYTE PROLIFERATION INHIBITORY FACTOR (PIF) IN ALCOHOLIC LIVER DISEASE.

(Eng.) Chen, T.; Leevy, C. M. (Martland Medical Center, Newark, NJ). *Clin. Exp. Immunol.* 26(1):42-45; 1976.

Lymphocyte proliferation inhibitory factor (PIF) was determined in the supernatants of phytohemagglutinin (PHA)-stimulated lymphocytes from alcoholic patients with normal liver (4), fatty liver (4), alcoholic hepatitis (6), and active Laennec's cirrhosis. PIF was assayed by determining inhibition of DNA synthesis in WI-38 human lung fibroblasts. PHA produced a 30- to 40-fold increase in the lymphocyte stimulation index, when added to lymphocytes from the patients with normal or fatty liver; there was only a 2- to 3-fold increase in this index when PHA was added to lymphocytes from patients with alcoholic hepatitis or active Laennec's cirrhosis. Autologous liver was without effect on the migration inhibition factor production in patients with normal (0.98 ± 0.8) and fatty liver (0.94 ± 0.11), but caused a significant decrease ($p<0.01$) in the migration inhibition index in patients with alcoholic hepatitis (0.73 ± 0.10) and active cirrhosis (0.74 ± 0.09). A twofold greater inhibition in thymidine incorporation into DNA by lung fibroblasts was observed in supernatants of PHA-stimulated lymphocytes from patients with alcoholic hepatitis or active Laennec's cirrhosis than from patients with normal or fatty liver. Decreased liver cell regeneration seen in some patients with alcoholic hepatitis may be due to increased elaboration of PIF.

3052 MODERN ASPECTS OF X-RAY DIAGNOSIS IN GASTROENTEROLOGY. (Ger.) Frik, W. (Abteilung Radiologie, Medizinische Fakultat, Rheinisch-Westfalische Technische Hochschule, Aachen, Goethestrasse 27-29, D-5100 Aachen, W. Germany). *Med. Klin.* 72(3):73-78; 1977.

GASTROINTESTINAL DISEASES

ESOPHAGUS

3124 ACHALASIA IN THREE SIBLINGS: A RARE OCCURRENCE.

(Eng.) London, F. A.; Raab, D. E.; Fuller, J.; Olsen, A. M. (Permanente Medical Group, San Francisco, CA). *Mayo Clin. Proc.* 52(2):97-100; 1977.

The case reports of three brothers with achalasia are presented. The first patient initially experienced symptoms of esophageal obstruction when he was 34, the second brother developed symptoms at 56, and the third at age 60 yr. The diagnosis of classic achalasia was confirmed in each brother by roentgenologic examination and by esophageal motility studies. Two patients were successfully treated by forceful dilation of the lower esophageal sphincter, and the third by esophagomyotomy. None of the 10 siblings of the three brothers had esophageal disorders, nor did any of the children of the patients. Although the patients were raised in the same home and all worked in iron mines, it appears unlikely that environmental factors were responsible for the development of this disease. The etiology of achalasia in siblings remains obscure, but a genetic origin (autosomal recessive) seems most likely.

3125 Candida ESOPHAGITIS: A PROSPECTIVE STUDY OF 27 CASES.

(Eng.) Kodsi, B. E.; Wickremesinghe, P. C.; Kozinn, P. J.; Iswara, K.; Goldberg, P. K. (Maimonides Medical Center, 4802 10th Ave., Brooklyn, NY 11219). *Gastroenterology* 71(5): 715-719; 1976.

A prospective study of *Candida* esophagitis was undertaken to determine the spectrum of this disease in a general hospital. Twenty-seven cases of *Candida* esophagitis occurred in 370 consecutive endoscopies performed in 1 yr. The diagnosis was established by finding white plaques on endoscopy, yeast organisms on microscopic examination of a direct smear from the plaques, and a serum agglutinin titer of at least 1:160. Of these 27 patients, 14 had esophageal symptoms. Twelve patients were reendoscoped after nystatin or nystatin and flucytosine therapy. Nine patients showed absence of lesions, a negative smear, and disappearance of symptoms. Control patients had no plaques on endoscopy, no yeast organisms on microscopical examination of esophageal brushings, and a positive titer in 4 to 17% of cases. A minimal agglutinin titer of 1:160 was found in 4-12% of two additional groups of controls. The absence of titer precluded a diagnosis of *Candida* esophagitis.

3126 RESULTS OF HELLER'S OPERATION FOR ACHALASIA OF THE OESOPHAGUS. THE IMPORTANCE OF HIATAL REPAIR.

(Eng.) Black, J.; Vorbach, A. N.; Collis, J. L. (Queen Elizabeth Hosp., Birmingham, England). *Br. J. Surg.* 63(12):949-953; 1976.

The results of cardiomyotomy for the repair of esophageal achalasia were evaluated in 108 patients, 55 of whom also underwent some type of hiatal reconstruction. Eleven of the latter patients underwent a formal plastic repair practiced for esophage reflux problems, while the remaining 44 patients underwent anterior crural suture. All operations were done by the abdominal approach, and all patie were followed up for a minimum of 4 yr. Seventy-o patients had entirely satisfactory results. Twent seven patients had recurrent dysphagia, and 20 patients had symptoms of reflux esophagitis. None of the 11 patients who underwent formal repair of the hiatus had reflux symptoms or dysphagia. Twen four of the 44 patients who had anterior suture an 36 of the 53 patients who underwent cardiomyotomy alone were asymptomatic 4 yr after the operation. Mild to severe reflux occurred in 11 patients with anterior suture and in 9 patients with cardiomyoto alone. The results suggest that much of the dysph following Heller's operation is due to occult gast esophageal reflux and can be avoided by a reflux-preventing procedure. Adequate hiatal repair afte myotomy is recommended.

3127 ESOPHAGEAL INTRALUMINAL pH RECORDING IN THE ASSESSMENT OF GASTROESOPHAGEAL REFLU AND ITS CONSEQUENCES.

(Eng.) Atkinson, M.; Van Gelder, A. (General Hosp., Nottingham NG1 6HA, England). *Am. J. Dig. Dis.* 22(4):365-370; 1977.

Intraluminal pH was determined in the lower esopha gus during a 3-hr period following a light meal an a consecutive 12-hr nocturnal period in 20 patient with typical symptoms and radiological evidence of gastroesophageal reflux and in 10 patients without such signs. Evidence of acid reflux was obtained in three patients without reflux during the postcibal period, but in only one during the nocturnal period. In contrast, 19 patients with evidence of reflux showed spells of high acidity, both in the postcibal and nocturnal periods. There was no clear correlation between the frequency of pain from gastroesophageal reflux over the preceding 2 weeks and the duration of high acidity in the nocturnal period. Those patients with endoscopic evidence of severe esophagitis showed a significantly longer duration of high esophageal acidity in the nocturnal period. Nocturnal exposure of th esophageal mucosa to acid is a major factor in the causation of reflux esophagitis.

3128 VALUE OF MERCURIC CHLORIDE SCINTIGRAPHY IN THE DIAGNOSIS OF ESOPHAGEAL CANCER.

STOMACH

38 POTENTIAL DIFFERENCE ACROSS THE NORMAL AND THE ABNORMAL GASTRIC MUCOSA IN MAN. (Eng.) ssenbocus, A.; Fitzpatrick, P.; Colin-Jones, D. G. rincess Alexandra Hosp., Woolloongabba, Brisbane, eensland, Australia). *Gut* 17(12):993-997; 1976.

e mucosal potential difference in the body of the omach was measured in 18 patients with gastric cers, 5 with gastritis, and 3 with pernicious emia and in 12 normal volunteers. The 12 normal bjects had a mean potential difference of -45.7 ± 6 mV. These levels were significantly lower in e patients with gastric ulcer (-32.4 ± 0.7 mV, 0.001), gastritis (-33.6 mV, $p<0.001$), and percious anemia (-35, -29, and -23 mV). In the 25 ditional patients, biopsies were taken and potenal difference was measured in the duodenal bulb d at five sites in the stomach to obtain a more rect correlation between histology and potential fference. The six patients with gastritis at the gh lesser curve had a significantly lower potenal difference (-4.8 mV) than did the patients thout gastritis at the same site (-15.8 mV, 0.01). In the latter group, the potential difrence at the high lesser curve was as low as that the antrum, and was invariably lower than that the high greater curve. This may imply an ineased permeability in the high lesser curve.

3139 ANTRAL GASTRIN CELLS: A CORRELATION BETWEEN THE NUMBER OF GASTRIN CELLS AND THE TOTAL CONCENTRATION OF GASTRIN IN SERUM AND IN ANTRAL MUCOSA. A PILOT INVESTIGATION. (Eng.) Asnaes, S.; Bjerregaard, B.; Malmstrom, J.; Hansen, O. H.; Hardt, F.; Johansen, A. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Scand. J. Gastroenterol.* 11(5):471-474; 1976.

Studies were carried out in 52 patients with different gastric diseases to correlate the number of gastrin-producing (g) cells with the gastrin concentration in the serum and in the antral mucosa. The gastrin cell number was determined by immunohistological staining of biopsies from the antral mucosa. In severe chronic gastritis, the pyloric mucosa contained few g-cells, whereas in normal and nonatrophic gastritis there were many g-cells. In pyloric mucosa containing few g-cells, the gastrin content (median, 4.8 µg/g tissue) was significantly lower ($p<0.01$) than that in pyloric mucosa containing many g-cells (median, 23.4 µg/g). The circulating fasting gastrin level was also significantly higher in the patients whose pyloric mucosa contained many g-cells (112 µg/ml) than in those whose mucosa contained few g-cells (44 µg/ml, $0.05>p>0.02$). It is not yet possible to estimate the total g-cell mass and thereby compare different clinical groups.

3140 EFFECT OF INTRADUODENAL ACID ON THE PRE- AND POST-VAGOTOMY BASAL GASTRIC SECRETION AND GASTRIN. (Eng.) Linares, C. A.; Falasca, C. A.; Sartorio, G. C.; Soto, R. J. (Univ. Buenos Aires Sch. Medicine, Aguero 1540-5, Buenos Aires, Argentina). *Surgery* 81(4):392-398; 1977.

Basal gastric secretion was studied in 10 normal subjects, 8 preoperative duodenal ulcer patients, 14 patients who had undergone truncal vagotomy and pyloroplasty, and 6 patients with highly selective vagotomies. Duodenal acidification lowered the gastric secretion and gastrin levels of normal subjects and preoperative ulcer patients. After both truncal and selective vagotomies, acid instillation did not inhibit gastric secretion, even when surgery had been performed 3 or more yr previously, but there was a decrease in gastrin levels. These results suggest that the secretory mechanism has a hormonal component mediated through the release of an enterogastrone, and a nervous one with vagal dependence. An intact gastric vagal innervation seems necessary to preserve sensitivity to hormonal inhibitors, whereas duodenal innervation does not influence inhibition. Highly selective vagotomy, therefore, does not appear to have any advantages over truncal section.

3141 EFFECT OF BETAZOLE ON SERUM GROUP I PEPSINOGEN LEVELS: RELATIONSHIP TO GASTRIC ACID OUTPUT IN UNOPERATED AND POSTOPERATIVE PATIENTS. (Eng.) Samloff, I. M.; Secrist, D. M.; Passaro, E., Jr. (Harbor General Hosp., 1000 West Carson St., Torrance, CA 90509). *Gastroenterology* 72(5, Part 1):845-848; 1977.

The effect of betazole on serum group I pepsinogen (PG I) levels and gastric acid output was compared in 245 unoperated patients (115 duodenal ulcer, 25 prepyloric ulcer, 32 gastric ulcer, 73 nonulcer) and 73 symptomatic postoperative patients (15 subtotal gastric resection, 28 vagotomy and gastric resection, 30 vagotomy and drainage). A negative serum PG I response (2-hr serum PG I level <92% of basal) occurred in 10 (4.1%) unoperated patients and in 31 (42.5%) postoperative patients. Seven (70%) of the former and 29 (93.5%) of the latter patients had a peak acid output of less than 10 mEq/hr, indicating that a negative serum PG I response is associated with a low peak acid output in both unoperated and postoperative patients. The peak acid output was greater than 10 mEq/hr in 93.1% of the 277 patients with a 2-hr serum PG I level of more than 92% of basal. Additional studies revealed that neither aspiration of gastric juice nor perfusion of the stomach with acid altered the serum PG I response. This suggests that topical acid does not modulate the effect of betazole on serum PG I levels. Finally, a negative serum PG I response has been shown to be paradoxical, in that gastric pepsin levels increase over basal levels concurrently with the decrease in serum PG I levels.

3142 GASTRIN LEVELS AND GASTRIC ACIDITY IN THE PATHOGENESIS OF ACUTE GASTRODUODENAL DISEASE AFTER BURNS. (Eng.) Rosenthal, A.; Czaja, A. J.; Pruitt, B. A. (Brooke Army Medical Center, Fort Sam Houston, TX). *Surg. Gynecol. Obstet.* 144(2): 232-234; 1977.

To define the pathogenetic relation between gastric acid secretion, serum gastrin, and acute gastr duodenal disease after burns, unstimulated gastric analyses were correlated with the findings of gastr duodenoscopy in 31 hemodynamically stable burned patients. Twenty-two patients had acute gastroduoden disease. Diffuse, superficial, gastroduodenal erosions were present in 17 patients; 5 additional patients had ulcerative lesions. Gastrin levels coul not be correlated with the incidence, severity or location of gastroduodenal disease. However, the mean gastric acidity was highest in patients with ulcerative disease (8.53 ± 4.96 mEq/hr), intermedia in those with superficial disease (2.80 ± 0.66 mEq/hr), and lowest in the nine patients with no diseas (1.19 ± 0.38 mEq/hr; correlation coefficient, $r = 0.41$, $p<0.05$). There was no correlation between the serum gastrin levels and gastric acid secretio The relative hyperacidity in patients with acute gastroduodenal disease suggests that acid may be o of the factors potentiating mucosal injury in these patients and may be particularly important in the evolution of life-threatening ulceration.

3143 AUTOIMMUNE ATROPHIC GASTRITIS WITH HYPERGASTRINEMIA. (Eng.) Reinhardt, J. D.; McCloy, R. M.; Blackwell, C. F. (Baptist Memorial Hosp., 899 Madison Ave., Memphis, TN 38146). *Sout Med. J.* 69(12):1551-1553; 1976.

The cases of three patients with chronic atrophic gastritis, achlorhydria, and parietal cell antibodies in the serum in whom elevated fasting level of serum gastrin were found are reported. The patients were women, ranging in age from 40 to 55 yr They were evaluated for persistent upper abdominal pain, without radiographic evidence of peptic ulce disease. Fiberoptic endoscopy revealed characteristic changes of chronic atrophic gastritis (i.e., diffuse chronic inflammation of the lamina propria and decreased numbers of parietal cells in the mucosa). Total achlorhydria was demonstrated afte a maximal histalog stimulus; however, serum levels of vitamin B_{12} and Schilling test values were norm in all three patients. Parietal cell antibodies were found in the serum in all patients in a dilution of 1:20-1:80. These cases represent autoimmu (type A) chronic atrophic gastritis and should be distinguished from chronic simple (type B) gastrit in which serum gastrin levels are normal and no parietal cell antibodies are found in the serum. Patients with autoimmune gastritis should be obser at frequent intervals for the occurrence of pernicious anemia or gastric carcinoma.

3144 GASTRIC MUCOSAL POLYPS IN PERNICIOUS ANAEMIA. (Eng.) Elsborg, L.; Andersen, Myhre-Jensen, O.; Bastrup-Madsen, P. (Aarhus Amtssygehus, DK-8000 Aarhus C, Denmark). *Scand. J. Gastroenterol.* 12(1):49-52; 1977.

Because of the high frequency of gastric polyps a gastric cancer among patients with pernicious anemia, 68 pernicious anemia patients were examined gastroscopically at regular intervals (3-6 months) for 4 yr. Biopsies were taken from the antral mucosa just orad to the pylorus and from the fundal mucosa just below the cardia; four or five biopsies were taken from each gastric polyp. Atrophic gastritis was confirmed in 91% of biopsied patients, and intestinal metaplasia of superficial epithelium and/or gland epithelium was found in one or more biopsy specimens in 54 of the 60 patients with atrophic gastritis. Gastric polyps not exceeding 2 cm in diameter, often with a slightly eroded surface, were seen in 25 patients. Multiple polyps were found in only nine of these patients. Follow-up examinations showed complete disappearance of the polyps in nine patients within a year or two, while the number of polyps was reduced during the observation period in two patients. New polyps were observed in five patients in whom gastroscopic examination had initially failed to reveal polyps. The number of previously observed polyps was increased in three patients. None of the polyps seen in the 25 patients underwent malignant transformation during the 4-yr period; by histological examination, they were classified as non-neoplastic "regenerative" benign polyps in an atrophic gastric mucosa. The authors conclude that if polyps of this type are asymptomatic and do not give rise to any mechanical obstruction, they can safely be followed up once or twice a year until disappearance occurs.

3145 DRUG THERAPY FOR POSTVAGOTOMY GASTRIC STASIS.

(Eng.) Sheiner, H. J.; Catchpole, B. N. (Perth Medical Center, Shenton Park, 6008, Perth Western Australia). *Br. J. Surg.* 63(8):608-611; 1976.

Therapy with bethanechol chloride and metoclopramide was assessed in six patients presenting with severe symptoms of gastric retention both in the early and late periods following truncal vagotomy with a drainage procedure. Therapy was initiated after mechanical obstruction of the gastric outlet was excluded by radiology. The administration of bethanechol chloride (2.5 mg, s.c.) produced gastric peristalsis in all patients, although three patients required a second dose. Improvement of symptoms occurred in five subjects. Two i.v. injections of 10 mg of metoclopramide (within a 15-min period) produced no peristalsis when given alone. In one patient, however, metoclopramide increased the gastric contractions that had been initiated by bethanechol.

3146 PYLORIC STENOSIS IN THE OXFORD RECORD LINKAGE STUDY AREA.

(Eng.) Adelstein, P.; Fedrick, J. (Dept. Regis Professor of Medicine, Oxford Univ., England). *J. Med. Genet.* 13(6):439-448; 1976.

The Oxford Record Linkage Study files (1966-1971) were used to identify 220 infants presenting with hypertrophic pyloric stenosis (IHPS), and the increased risk of recurrence within families was studied (siblings born 1965-1972). The overall incidence is 2.56 per 1,000 live births (222/82,761 cases). The study was undertaken to identify the relationship of environmental factors with genetic make-up in the development of IHPS. Male infants (186/220 cases) were at higher risk than female infants; the male to female ratio was 5.47:1. There was no variation in birth weight, and only among the females was a lack of premature pyloric infants ($p>0.01$) seen. There was an inverse relation between gestation and age on admission of the infant to hospital. There was a distinct seasonal variation in time of birth, with highest incidence occurring in infants born in July-September. A variation in incidence with geographical area of residence was seen. The cities (1.98/1,000 infants) had lower rates of IHPS than the adjacent rural (2.58/1,000 infants) or small urban (2.92/1,000 infants) areas. The highest incidence was reported in the town of Wallingford (9.3/1,000 cases). The risk of IHPS was not greatest among firstborns, but among second children (85/1,000 cases). Of the other major factors studied, maternal age (20-24 yr), social class (upper), and rhesus-negative mothers ($p<0.02$) showed a definite association with incidence of IHPS. Legitimacy, religion, maternal origin, and blood group were not correlated with the incidence of IHPS.

3147 GASTRIC VARICES WITHOUT ESOPHAGEAL VARICES. AN IMPORTANT PREENDOSCOPIC DIAGNOSIS.

(Eng.) Rice, R. P.; Thompson, W. M.; Kelvin, F. M.; Kriner, A. F.; Garbutt, J. T. (Duke Univ. Medical Center, Durham, NC 27710). *JAMA* 237(18):1976-1979; 1977.

The cases of four patients with gastric varices presenting as a fundal mass without any demonstrable esophageal varices are presented. The first three patients (a 40-yr-old woman, a 61-yr-old man, and a 42-yr-old man) had histories of alcoholism. All patients presented with upper gastrointestinal or rectal bleeding. The first patient had severe chronic pancreatitis and died from hemorrhage of one of the pancreatic vessels. The finding of fundal varices by upper gastrointestinal examination was confirmed at autopsy. The second patient had a 25-yr history of recurrent upper gastrointestinal hemorrhage. The presence of fundal varices was confirmed by an upper gastrointestinal series and angiography. The splenic vein was patent, and there was evidence of chronic hepatitis. Although there was a history of heavy alcohol consumption in the past, there was no cirrhosis. Angiography showed no anastomoses between the gastric and retroperitoneal veins. In the third patient, angiography showed a large spleen, with splenic vein obstruction and large gastric varices. A liver biopsy specimen demonstrated cirrhosis. Endoscopy showed prominent folds in the fundus, with intact mucosa. The fourth patient, a 22-yr-old woman with no history of alcohol consumption, had a 13-yr history of abdominal pain. She had guaiac-positive stools and a low hemoglobin level. An abdominal roentgenogram demonstrated gross pancreatic calcification. Upper gastrointestinal studies demonstrated filling defects in the fundus. The appearance of the varices in this patient was round, smooth submucosal projections; in the other three patients, the varices had the appearance of a polypoid mass in the posterior aspect of the fundus. In patients 3 and 4, a double contrast examination of the stomach was done using high-density barium and gas-releasing tablets. This technique was superior to the conventional barium meal in that it was easier to determine whether the mucosa was intact. The roentgenographic demonstration of submucosal polypoid filling defects in the fundus of patients with pancreatic or liver disease should suggest gastric varices, even in the absence of esophageal varices.

STOMACH

Peptic Ulcers

3193 HISTAMINE AND PEPTIC ULCER: A PROSPECTIVE STUDY OF MUCOSAL HISTAMINE CONCENTRATION IN DUODENAL ULCER PATIENTS AND IN CONTROL SUBJECTS SUFFERING FROM VARIOUS GASTROINTESTINAL DISEASES. (Eng.) Troidl, H.; Lorenz, W.; Rohde, H.; Hafner, G.; Ronzheimer, M. (Chirurgische Univ.-Klinik, Robert-Koch-Str. 8, D-3550 Marburg a.d. Lahn, W. Germany). *Klin. Wochenschr.* 54(19):947-956; 1976.

A prospective study of histamine content of the body of the stomach was carried out in 31 controls, 18 patients with duodenal ulcer, and 51 patients with various gastrointestinal diseases. The median histamine content was 43 μg/g in normal male controls, while in duodenal ulcer patients, the levels were significantly lower by about 30%. In the other patients (gastric ulcer, hiatal hernia, gastric carcinoma, cholecystitis, gastric erosions, Zollinger-Ellison syndrome, atrophic gastritis, pancreatitis, esophageal varices due to portal vein cavernoma, and alimentary obesity), the median histamine concentrations in gastric mucosa ranged between 13.3 and 95.8 μg/g. Since in most species it is extremely difficult to alter the mucosal histamine concentration by any form of treatment, the diminished histamine content of the gastric mucosa in patients with duodenal ulcer seems remarkable. Among several possible explanations, the most likely is that histamine release is increased in duodenal ulcer disease.

3194 HISTAMINE AND PEPTIC ULCER DISEASE: HISTAMINE METHYLTRANSFERASE ACTIVITY IN GASTRIC MUCOSA OF CONTROL SUBJECTS AND DUODENAL ULCER PATIENTS BEFORE AND AFTER SURGICAL TREATMENT. (Eng.) Barth, H.; Troidl, H.; Lorenz, W.; Rhode, H.; Glass, R. (Surgery Clinic of the Univ., D-3550

Marburg/Lahn, Robert-Koch-Strasse 8, Marburg, W. Germany). *Agents Actions* 7(1):75-79; 1977.

Histamine methyltransferase (HMT) activity was determined by a modified isotope assay in biopsy specimens from gastric mucosa of 15 male control subjects, 18 male duodenal ulcer patients, and 20 male patients after various gastric operations. Enzymic activity of the control subjects, who were "healthy" with respect to their upper gastrointestinal tract, was 70.4 ± 12.8 pmol/(min/mg protein). In duodenal ulcer patients, HMT activity was significantly lowered by 15%; following selective vagotomy with pyloroplasty, a significant increase of 14% was observed, as compared to controls. The difference between values before (59.9 ± 13.3 pmol) and after (80.4 ± 11.7 pmol) this operation was highly significant ($p<0.001$). Experiments in a small number of patients showed that after other modifications of vagotomy, elevated HMT activities were also found; whereas after resection procedures, such changes of enzymic activity did not occur. The low gastric HMT activity of duodenal ulcer patients could play a role in the pathogenesis of a chronic peptic ulcer by being responsible for reduced histamine inactivation and, as a consequence, enhanced acid secretion. Vagotomy seemed to influence acid secretion in human subjects, not only by direct effects on the parietal cells, but also by an activation of histamine catabolism. One patient, who despite complete vagotomy showed both no reduction in acid secretion and a low gastric HMT activity, may be the representative of a new population of peptic ulcer patients.

3195 KINETICS OF DUODENAL ULCER HEALING: EFFECT OF TREATMENT WITH CIMETIDINE. (Eng.) Domschke, W.; Domschke, S.; Lux, G.; Demling, L. (Dept. Medicine, Univ. Erlangen-Nurnberg, Krankenhausstr. 12, D-8520 Erlangen, W. Germany). *Acta Hepatogastroenterol.* 23(6):441-443; 1976.

To study the kinetics of ulcer healing, ulcer size was assessed endoscopically before and after cimetidine or placebo therapy in a double-blind trial of 12 duodenal ulcer patients. The patients received cimetidine (200 mg, t.i.d., p.o.) or placebo, and endoscopy was performed at weekly intervals during treatment. Duodenal ulcer healing was significantly more rapid in cimetidine-treated patients than in those receiving the placebo ($p<0.0005$); the half-times of ulcer healing were about 6 days on cimetidine compared to about 20 days on placebo. No untoward clinical or laboratory effects (i.e., changes in hemoglobin, WBC count, neutrophils, platelets, blood-urea, alkaline phosphatase, SGOT, or SGPT) attributable to cimetidine were recorded in any patient between 0 and 4 weeks of treatment.

3196 CONTROLLED TRIAL OF DUOGASTRONE IN DUODENAL ULCER. (Eng.) Davies, W. A.; Reed, P. I. (Wexham Park Hosp., Slough, Berkshire, England). *Gut* 18(1):78-83; 1977.

A double-blind, placebo-controlled trial of carbenoxolone in a daily dose of 200 mg for 12 weeks was carried out in 40 ambulatory patients with endoscopically diagnosed duodenal ulcers; 34 of the patients were available for final analysis. Each patient was seen every 2 weeks and endoscoped at 4, 8, and 12 weeks. Serum carbenoxolone was measured at each visit. Complete ulcer healing occurred in a significantly greater number of patients receiving carbenoxolone than placebo, the significance being greater after 4 and 8 weeks of treatment ($p<0.01$) than at 12 weeks ($p<0.02$). While significant symptomatic improvement also was achieved ($p<0.05$) after 12 weeks on carbenoxolone, there was a much closer correlation between ulcer healing and symptom relief; 69% of the patients on carbenoxolone returned to normal, compared with 22% of controls ($p<0.02$). Rise of systolic blood pressure and reduction in serum potassium levels, especially during the last 4 weeks, were the most common effects noted in patients taking carbenoxolone, and five patients required thiazide diuretics and potassium supplements. Higher serum carbenoxolone levels were found in patients with healed ulcers, as well as in those with more marked side-effects. It is concluded that carbenoxolone is highly effective in healing duodenal ulcers.

3197 THE EFFECT OF METIAMIDE ON THE PROLONGED SERUM GASTRIN RESPONSE TO FEEDING OBSERVED IN PATIENTS WITH DUODENAL ULCER. (Eng.) Blair, E. L.; Grund, E. R.; Reed, J. D.; Sanders, D. J.; Thompson, M. H.; Venables, C. W. (Dept. Physiology, Univ. Newcastle upon Tyne, Newcastle upon Tyne, England). *Br. J. Surg.* 63(8):599-602; 1976.

The serum gastrin response to a meal was studied in 11 healthy controls and 16 patients with duodenal ulcer, and the effect of metiamide on this response was investigated. The ulcer patients consisted of nine patients with a mean ulcer history of 9 yr (group 2) and seven patients with an ulcer history of 10 yr (group 3). The mean serum gastrin concentration rose following the standard breakfast in normal subjects from a fasting value of 33.9 ± 6.8 pg/ml to a peak value of 69.4 ± 11.4 pg/ml within 1 hr of the end of the meal, and then fell progressively. By 3 hr of the end of the meal, the mean serum gastrin concentration was not significantly different from the fasting value. In group 2, the mean gastrin concentration increased from 45.6 ± 10.3 pg/ml to 80.8 ± 11.2 pg/ml in the first 15 min after the meal. In these patients, the peak concentration was sustained throughout the 3-hr test period. Group 3 patients had a similar response. The p.o. administration of labeled metiamide (300 mg; 25 μCi tritium/100 mg metiamide) in five group 3 patients had no effect on this response. It is concluded that the control of gastrin release is defective in duodenal ulceration, which may be due to a failure of the antral pH feedback mechanism. Gastrin may be a primary pathogenetic factor in duodenal ulceration.

3198 LONG-TERM EFFECTS AND AFTER-EFFECTS OF TREATMENT OF DUODENAL ULCER WITH METIAMIDE. (Eng.) Saunders, J. H. B.; Wormsley, K. G. (Dept.

Therapeutics, Univ. Dundee, Dundee, Scotland). *Lancet* 1(8015):765-767; 1977.

Three therapeutic regimens were investigated to determine the best way of treating duodenal ulceration with metiamide and cimetidine. Twenty patients received a 28-day course of metiamide (1 g/day); at the end of treatment the ulcers were determined to be healed endoscopically. Eight patients then received 400 mg of metiamide at night before sleep, while the remaining patients received placebo. This regimen did not prevent recurrence, and the median interval before the return of symptoms and endoscopic relapse was 7.5 months after cessation of full daily dose therapy; this was not significantly different from the interval in the patients receiving placebo. Another group of seven patients received metiamide throughout the day, as well as at night, in a dose of either 800 mg or 1 g/day, for 4-15 months. At the end of the first 28 days of treatment, all ulcers were healed, and recurrence was prevented by continued administration. Cessation of treatment was followed by rapid relapse or asymptomatic ulcer recurrence. Five additional patients received 1 g metiamide daily for 1 month, after which their ulcers were healed. The patients were followed at monthly intervals and re-endoscoped at the time of relapse; at this time, they received a further course of 1 g/day of metiamide or cimetidine for another month. Treatment was continued until ulcer healing was complete. In this group, the median time to relapse was 4 months after the first course of treatment and shortened significantly, to 2 months, after the second course of treatment. Symptomatic relief was slower in onset in response to the first course (2 days). The treatment of duodenal ulcer with H_2-receptor antagonists requires further investigation.

3199 ULTRASTRUCTURE OF PARIETAL CELLS BEFORE AND AFTER PROXIMAL GASTRIC VAGOTOMY IN DUODENAL ULCER PATIENTS. (Eng.) Aase, S.; Roland, M.; Olsen, B. R. (Anatomical Inst., Univ. Oslo, Oslo, Norway). *Scand. J. Gastroenterol.* 11(1):55-64; 1976.

The ultrastructure of parietal cells before and after proximal gastric vagotomy (PGV) was studied in four duodenal ulcer patients to determine whether the reduced acid secretion, observed after PGV, is accompanied by intracellular changes in parietal cells. All patients showed a significant decrease in acid output, as well as in volume of gastric juice, after PGV. Stereological analysis of electron micrographs showed that the volume density of microvilli 10 days after PGV was significantly reduced by about 50%. There was a significant increase in the percent relative volume of the rough endoplasmic reticulum (from an average value of 0.8 to 2.9 after PGV). There was a significant decrease of about 55% in the secretory membrane surface. The surface density of the rough endoplasmic reticulum was also significantly increased. The most striking morphological feature 10 days after PGV was the appearance of membranous whorls and flattened sacs in the cytoplasm surrounding the intracellular canaliculi. Before PGV, tubulo-vesicular membranes were about 16,000 cm^2/cm^3; 10 days after PGV, the corresponding value was about 41,000 cm^2/cm^3. In most cells, the mitochondria appeared less dense, and their cristae were more easily distinguished, 10 days after PGV than before the procedure. Three months after the operation, the relative mitochondrial volume was about 37%; that of dense bodies was 6%; microvilli accounted for about 8%; and the rough endoplasmic reticulum accounted for less than 1% of the total cell volume. Compared with the value found before PGV, the increase in the relative volume of dense bodies 3 months after the operation was statistically significant. The surface density of tubulo-vesicular membranes had decreased to 22,000 cm^2/cm^3. The area of canalicular membrane showed a significant decreased from about 31,000 cm^2/cm^3 to 24,000 cm^2/cm^3. The possibility that qualitative changes within the canalicular membrane 3 months after PGV are important for the observed reduction in acid output, in addition to the reduced amount of canalicular membrane, cannot be excluded. The relative volume of dense bodies was more than doubled 3 months after PGV, and the observed removal of tubulo-vesicular membranes between the 10 days and the 3-month stage may therefore be due to lysosomal activity.

SMALL INTESTINE

217 MASSIVE INTESTINAL INFARCTION IN YOUNG WOMEN: COMPLICATION OF USE OF ORAL CON-
RACEPTIVES? (Eng.) Koh, K. S.; Danzinger, R. G.
Dept. Surgery, Univ. Manitoba, Winnipeg, Manitoba
2H 2A6, Canada). *Can. Med. Assoc. J.* 116(5):513-
15; 1977.

he cases of two women with massive intestinal in-
arction due to occlusion of the celiac, superior
esenteric, and inferior mesenteric arteries are
resented. Both patients, 37 and 29 yr old, were
smokers and had taken oral contraceptives for 5 and
yr, resp. Both patients presented with epigastric
r lower abdominal pain associated with nausea and
omiting. Both patients subsequently developed
signs of peritonitis. In the first patient, laparotomy revealed peritonitis with gangrene of almost the entire small bowel plus the sigmoid colon; all but the duodenum and the distal 10 cm of terminal ileum were resected. She subsequently developed arterial occlusion in the leg necessitating amputation, and a cecal fistula that persisted despite three attempts at closure. The right side of the transverse colon was removed at a second laparotomy, and total parenteral nutrition was begun. The patient died of *Candida albicans* septicemia. Autopsy revealed thrombosis of the celiac, superior mesenteric, inferior mesenteric, and common iliac arteries and premature atherosclerotic changes in the common iliac arteries. Laparotomy in the second patient revealed a gangrenous, perforated ileal loop, requiring resection of 122 cm of ileum. A

second laparotomy disclosed a jejunocolic fistula, complete atrophy of the remaining small intestine and right transverse colon, and perforation of the ischemic cecum. The cecum was oversewn, and a "mucus fistula" was created in the ascending colon; the gastrointestinal contents thus passed from the proximal jejunum to the distal transverse colon. The patient survived and is receiving supplemental parenteral nutrition. Oral contraceptives could not be proven to be a causative factor; although such an association is uncommon, it should be considered in young women with abdominal pain.

3218 ANGIOGRAPHIC DIAGNOSIS OF SMALL INTESTINAL INTUSSUSCEPTION.

(Eng.) Lande, A.; Schechter, L. S.; Bole, P. V. (Jersey City Medical Center, Jersey City, NJ 07304). *Radiology* 122(3): 691-693; 1977.

The angiographic findings in a patient with a small intestinal intussusception are presented. The intussusception occurred postoperatively in a 22-yr-old man following a fall. The patient underwent abdominal angiography to investigate continuous postoperative abdominal distension and significant electrolyte imbalance. This procedure suggested intussusception, and reexamination revealed an antegrade ileoileal intussusception measuring 12-15 cm in length in the proximal ileum. Several adhesions binding the intussusception were lysed, followed by spontaneous reduction of the intussusception. The angiographic configuration of the small intestinal intussusception was compared to a series of opposing angles with a beak-like conglomeration of vasa recta attached to its distal and proximal end.

3219 SIGNIFICANCE OF PNEUMATOSIS CYSTOIDES INTESTINALIS AFTER JEJUNOILEAL BYPASS.

(Eng.) Feinberg, S. B.; Schwartz, M. Z.; Clifford, S.; Buchwald, H.; Varco, R. L. (Univ. Minnesota Hosp., Box 292 Mayo Memorial Bldg., Minneapolis, MN 55455). *Am. J. Surg.* 133(2):149-152; 1977.

The significance of radiographically demonstrable pneumatosis after jejunoileal bypass was evaluated in 148 patients. Pneumatosis intestinalis was demonstrated on postoperative abdominal scout films on 28 occasions in 24 patients with jejunoileal bypass. Pneumatosis intestinalis was confined to the right colon. Abnormal clinical findings were present in 22 of the 28 episodes. The symptoms included nausea (11 patients), vomiting (12), low grade fever (5), abdominal pain (6), and abdominal distention (2). The stool frequency did not increase with pneumatosis. Similar clinical findings of nausea, vomiting, and/or fever were seen in seven of these patients at a time when there was no radiological evidence of pneumatosis. It appears that pneumatosis intestinalis does not represent a specific sign for bypass enteritis.

3220 POSSIBLE CONNECTION BETWEEN INFECTIONS WITH Yersinia enterocolitica AND REGIONAL ENTERITIS. PRELIMINARY CUMMUNICATION.

(Ger.) Antalik, J. (Rontgenabteilung des Bezirkskrankenhauses, Ounz Nove Zamky, Czechoslovakia). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 125(6):510-514; 1976.

Microbiological, pathologicoanatomical, and clinical pictures of infections with *Yersinia enterocolitica* are outlined. Distinct radiological similarity was detected between enteric infection with *Y. enterocolitica* and Crohn's disease in three patients. No pathologicoanatomical substratum of the x-ray findings has yet been discovered. Only investigation of additional cases, long-term supervision, and development of Crohn's disease from infection with *Y. enterocolitica* will prove a possible connection between the two diseases.

3221 CHOLESTEROL METABOLISM IN PATIENTS WITH RESECTION OF ILEUM AND PROXIMAL COLON.

(Eng.) Ho, K. J.; Bondi, J. L. (Univ. Alabama in Birmingham, Medical Center, University Station, Birmingham, AL 35294). *Am. J. Clin. Nutr.* 30(2): 151-159; 1977.

Compartmental analysis of the disappearance curve of serum cholesterol specific activity after the i.v. administration of a tracer dose of cholesterol-4-^{14}C was carried out in five patients with resection of the distal small intestine, cecum, and proximal colon The data fit a two compartment model in all five cases, with the rapidly exchangeable pool of 16.6 ± 3.2 g (60% of the mean of 15 normal controls) and the slowly exchangeable pool of 31.5 ± 10.9 g (65%). The reduction of the pool sizes was associated with a shorter mean transit time of cholesterol (22.15 ± 8.07 days, 40%) and increased turnover rate (2.42 ± 0.72 g/day, 172%). Direct fecal analysis for the neutral sterols and bile acids derived from the exchangeable pool confirmed the turnover rate obtained from the compartmental anaylsis. The increased fecal excretion was mainly in the bile acid fraction. The results suggest that the ileal and proximal colon resection results in bile acid malabsorption, which, in turn, increases hepatic cholesterol and bile acid synthesis. The synthetic rates, however, could not compensate totally for the excretory rate. Therefore the pool size decreased to a new low steady state of equilibrium.

3222 BYPASS ENTEROPATHY: INTESTINAL AND SYSTEMIC MANIFESTATIONS FOLLOWING SMALL-BOWEL BYPASS.

(Eng.) Drenick, E. J.; Ament, M. E.; Finegold, S. M.; Corrodi, P.; Passaro, E. (Veterans Admin. Wadsworth Hosp. Center, Wilshire and Sawtelle Blvd., Los Angeles, CA 90073). *JAMA* 236(3):269-272; 1976.

Intestinal and systemic manifestations following jejunoileal bypass surgery were studied in 26 patients. Clinical assessment, determination of nitrogen balance, fecal protein loss by chromated ^{51}Cr serum albumin excretion, 24-hr urinary oxalate excretion, histologic study of resected and needle biopsy specimens, quantitative studies of aerobic and anaerobic flora, and mass spectroscopy of enteric gas were carried out. Twenty-three patients had end-to-end procedures, and the other three patients had an end-to-side procedure. Diarrhea with irregular exacerbations occurred in all of the 15 patients who developed enteropathy and in only 1 of the 11 patients without enteropathy. Recurrent fever, arthralgia, skin lesions, and pseudo-obstruction occurred only in patients with enteropathy. Surgical exploration, performed in six patients, revealed greatly dilated small and large bowel loops. Histological examination of the mucosa of the bypassed segment in five patients revealed blunting of the villi, increased number of lymphocytes and plasma cells in the lamina propria, and increased mononuclear cells in transmigration and mitotic figures in the epithelium, which had lost its polarity. The bacterial population in the excluded loops of six patients was highly variable in species and number, ranging from a mixed aerobe-anaerobe flora to pure cultures of *Escherichia coli*. Abnormally high fecal protein excretion (up to 16 g/day) was found in four of five patients with enteropathy and in none of three patients without enteropathy. Of 14 patients with enteropathy in whom baseline and sequential liver biopsies were performed, 12 manifested increasing steatosis, and in 4 of these, fibrosis became noticeable. Of 10 patients without enteropathy in whom biopsies were done, 6 had similar fatty changes; fibrosis developed in 1 heavy drinker, while in 4 patients, the liver remained unaltered. There was no distinct correlation between steatosis and enteropathy. Hyperoxaluria in excess of 40 mg/24 hr was seen in 11 of 23 patients. Of these, only six had evidence of overt enteropathy, suggesting etiologic mechanisms other than the inflammatory process. This study indicates that jejunoileal bypass may produce an enteropathy in the excluded segment of small bowel that can elicit intestinal disorders and manifestations of a systemic illness with complications in distant organs.

3223 ABNORMALITIES OF CIRCULATING 25-OH VITAMIN D AFTER JEJUNAL-ILEAL BYPASS FOR OBESITY: EVIDENCE OF AN ADAPTIVE RESPONSE. (Eng.) Teitelbaum, S. L.; Halverson, J. D.; Bates, M.; Wise, L.; Haddad, J. G. (Jewish Hosp., 216 South Kingshighway, St. Louis, MO 63110). *Ann. Intern. Med.* 86(3):289-293; 1977.

Circulating levels of 25-OH vitamin D were measured in 44 patients who had undergone small intestinal bypass for obesity. Sixty-one percent had hypovitaminosis D. A rapid rate of weight loss was attended by lower concentrations of the vitamin D metabolite. This adaptive response was also reported for circulating total calcium, magnesium, albumin, and alkaline phosphatase. The serum concentration of 25-OH vitamin D, calcium, and magnesium was negatively related to circulating immunoreactive parathyroid hormone, which was high in 6 of 28 patients measured. Impaired intestinal absorption of 25-OH vitamin D was seen in two patients. Seasonal variation had no influence on the relation between serum 25-OH vitamin D and postoperative interval. Despite apparent abnormalities of mineral metabolism in the group studied, there was little evidence of densitometrically evaluated bone disease. The bone densities of 2 of 32 patients were below the 95% confidence limit. Oral administration of a single dose of 25-OH vitamin D_3 in capsular form (5 μg/kg) to these two patients resulted in subnormal elevations of serum 25-OH vitamin D. Skeletal biopsies of three of six patients showed increased numbers of osteoclasts or increased osteoid content. It is concluded that small intestinal bypass results in at least transient deficits of circulating 25-OH vitamin D; prolonged observation is suggested to discover whether this procedure promotes clinically significant skeletal abnormalities.

3224 STUDY OF THE ELECTRICAL POTENTIAL DIFFERENCE BETWEEN ILEAL MUCOSA AND SKIN IN THE CHILD. EFFECT OF A REDUCTION OF SODIUM INTAKE. (Fre.) Ricour, C.; Feydy, P.; Arhan, P. (Hopital des Enfants-Malades, 149 rue de Sevres, 75730 Paris Cedex 15, France). *Ann. Chir. Infant.* 18(1):5-10; 1977.

SMALL INTESTINE

Malabsorption

3248 PLASMA TRIGLYCERIDE INCREASE AFTER ORAL FAT LOAD IN MALABSORPTION DURING EARLY CHILDHOOD. (Eng.) Fallstrom, S. P.; Nygren, C. O.; Olegard, R. (Dept. Pediatrics I, Ostra Sjukhuset, 41685 Goteborg, Sweden). *Acta Paediatr. Scand.* 56(1):111-116; 1977.

The effect of oral fat load on the triglyceride concentration in plasma was studied to evaluate the use of this test in the diagnosis of fat malabsorption during early childhood (1 month to 3 years of age). Thirty-two children with various fat malabsorption syndromes, 8 children with transient growth retardation, and 29 controls were tested for plasma triglycerides before, and after (at 2 and 4 hr) a test meal of 2 g of neutral fat per kg. Two hours after the test meal, control children over 4 months of age showed the largest increase in plasma triglycerides, with a mean of 1.34 mM; it was always greater than 0.50 mM, or 60% of the fasting level. Some of the control children younger than 4 months showed slightly smaller increases, but they were always greater than 0.30 mM, or 40% of the fasting levels. Children suffering from defective digestion had no significant increases at 2 hr, usually less than 0.20 mM, or 23% of fasting levels. Children with gluten enteropathy had significantly higher fasting levels than controls ($p<0.01$), but there were no obvious increases until after 4 hr, and they were always less than 0.75 mM. Children with transient growth retardation showed increases similar to those observed in the controls. Using the above criteria, 30/32 (94%) of the children with fat malabsorption syndromes showed abnormal plasma triglyceride increases of less than 0.30 mM and 0.50 mM before and after 4 months of age, resp. Finally, a greater percentage of the patients with malabsorption produced abnormal results with the triglyceride test than with two other common tests, xylose (76%) and fecal fat (55%).

3249 DUODENAL BILE ACID CONCENTRATIONS IN FAT MALABSORPTION SYNDROMES. (Eng.) Westergaard, H. (Rigshospitalet, Blegdamsvej 9, DK 2100 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12(1):115-122; 1977.

The relationship of meal-stimulated bile acid concentrations in the duodenum to fat absorption was observed in 38 healthy persons and in 138 patients with various gastrointestinal diseases, sometimes associated with fat malabsorption characterized by steatorrhea. In controls, the mean duodenal bile acid concentration was 10.8 mM/1. Below normal bile acid concentrations consistently resulted in steatorrhea in most patients with gastric disease, except in those with duodenal ulcers. Low bile acid concentrations accompanied by steatorrhea were frequently observed in patients with gastric surgery, cholestasis, the stagnant loop syndrome, or ileal disorders. Bile acid concentrations appeared deceptively low in duodenal ulcer patients and in patients with cholecystectomy, due to increased secretory volumes. Normal bile acid concentrations were observed in patients with pancreatic disease, since fat malabsorption is due to inefficient lipolysis. In patients with the stagnant loop syndrome, unconjugated bile acids were demonstrated, indicating abnormal intestinal flora. These results suggest that measurement of total and individual bile acid concentrations stimulated by test meals can be useful in the diagnosis of certain fat malabsorption syndromes.

3250 IDIOPATHIC BILE ACID CATHARSIS. (Eng.) Thaysen, E. H.; Pedersen, L. (Aalborg Sygehus, POB 561, DK 9100 Aalborg, Denmark). *Gut* 17(12):965-970; 1976.

The case reports of three patients in whom idiopathic bile acid malabsorption was responsible for chronic diarrhea are presented. The patients included a 57-yr-old woman with a 35-yr history of diarrhea, a 35-yr-old man with a 15-yr history, and a 49-yr-old woman who had diarrhea all of her life. The diarrhea in the three patients was not associated with ileopathy nor with any other disorder allied to diarrhea. Screening for bile acid malabsorption was performed by means of the ^{14}C-cholylglycine breath test, and kinetics and pool size of chenodeoxycholic acid were assessed by the isotope dilution technique. In the first two patients, the breath test indicated bile acid malabsorption, whereas the third patient had a marked pathological breath $^{14}CO_2$, but a normal 24 hr ^{14}C fecal radioactivity. Six months later, fecal radioactivity in this patient was also found to be abnormal. The chenodeoxycholic acid (CDC) half-life in the three patients was 0.8, 1.1, and 0.8 days, resp. (control 3.0 days), and the CDC synthesis rates were 1.7, 1.6, and 6.8 mmol/24 hr, resp. (control 0.4 mmol/24 hr). The diarrhea resolved immediately in all three patients when they were treated with cholestyramine (2-3 g questrane t.i.d.). The symptoms returned in all patients whenever treatment was withdrawn. Idiopathic catharsis should be suspected in patients with unexplained chronic diarrhea, and especially in those with a diagnosis of irritable colon with diarrhea.

3251 THE 15 g D-XYLOSE ABSORPTION TEST: ITS APPLICATION TO THE STUDY OF COELIAC DISEASE.

(Eng.) Stevens, F. M.; Watt, D. W.; Bourke, M. A.; McNicholl, B.; Fottrell, P. F.; McCarthy, C. F. (Regional Hosp., Galway, Ireland). *J. Clin. Pathol.* 30(1):76-80; 1977.

The potential of the D-xylose absorption test as a screening method for occult adult celiac disease was investigated in 17 untreated adult celiac disease patients, 21 treated celiac patients, and 30 nonceliac disease patients. Each patient received a p.o. load of 15 g of D-xylose, and serial blood levels were determined. A statistically significant difference in xylose blood levels was found between untreated celiac and nonceliac patients at all times after D-xylose administration, but a complete separation between these two groups occurred only after 75 min. The reproducibility of absorption was assessed by repeating the test in 16 subjects (4 untreated patients, 3 treated patients, and 9 controls). The 95% confidence limits were narrowest at 75 and 90 min. The D-xylose test will probably be useless in screening asymptomatic relatives of patients with celiac disease, but it may be used to demonstrate changes in intestinal absorptive function in a single individual.

3252 DNA SYNTHESIS BY JEJUNAL MUCOSA IN RESPONSIVE AND NON-RESPONSIVE COELIAC DISEASE.

(Eng.) Jones, P. E.; Peters, T. J. (Royal Postgraduate Medical Sch., London W12 OHS, England). *Br. Med. J.* 1(6069):1130-1131; 1977.

DNA synthesis by jejunal biopsy specimens from 22 patients with adult celiac disease and from 13 controls was measured by an organ culture technique to determine the enterocyte production rate in celiac disease patients. The DNA synthesis rate in the mucosa of the 6 patients with untreated celiac disease was almost eight times that in specimens from the 13 control patients with normal mucosa (mean, 92 ± 16 counts/min/μg DNA versus 13 ± 0.7 cpm/μg DNA, $p<0.01$). The seven patients whose jejunal mucosa remained flat despite gluten withdrawal showed a rate of DNA synthesis (34 ± 1.1 cpm/μg DNA) significantly lower than that of the untreated celiac group ($p<0.05$). The nine patients with celiac disease in whom gluten withdrawal had improved the jejunal morphology had a DNA synthesis rate similar to that of the controls. Impaired enterocyte production in nonresponsive celiac disease may be responsible for the failure to regenerate villi after gluten withdrawal.

3253 PATCHINESS AND DUODENAL-JEJUNAL VARIATION OF THE MUCOSAL ABNORMALITY IN COELIAC DISEASE AND DERMATITIS HERPETIFORMIS.

(Eng.) Scott, B. B.; Losowsky, M. S. (St. James' Hosp., Leeds, England). *Gut* 17(12):984-992; 1976.

Studies were designed to document the incidence and degree of patchiness of mucosal abnormality in celiac disease (CD) and dermatitis herpetiformis (DH), to compare duodenal with jejunal biopsies in control subjects, and to assess variation between these two sites in patients with CD and DH. As judged by both stereomicroscopy and subjective histology, patchiness occurred frequently in both CD and DH patients. In most cases, the difference of abnormality was of only one grade, but in approximately 25% as assessed by stereomicroscopy and 10% as assessed by histology, the difference was of two or more grades. In 19 control subjects with normal small bowel mucosa, the variation of the mucosal appearance between the duodenum and proximal jejunum was studied. No significant difference of villous and crypt measurements or of apparent villous "bridging" and "branching" between these two sites was found, if only well-oriented sections were studied. The stereomicroscopic appearances were also similar at these two sites, although villi tended to be broader in the duodenal biopsies. The duodenal-jejunal variation was also studied in CD and DH patients and, although by both stereomicroscopy and subjective histology the appearances were similar in most patients, in approximately 33%, the duodenal abnormality was the more severe; the jejunal abnormality was more severe in approximately 15%. It is concluded that multiple, precisely located biopsies of both the duodenum and proximal jejunum are invaluable in the investigation of small bowel disease and in assessing response to treatment.

3254 DIGESTIVE INTOLERANCE TO COW'S MILK PROTEIN. RECENT IMMUNOLOGICAL DATA.

(Fre.) Scheinmann, P.; Paupe, J. (CHU Necker-Enfants-Malades, 156 rue de Vaugiraud, 75780 Paris Cedex 15, France). *Rev. Fr. Allergol.* 16(3):157-161; 1976.

Recent immunological data on digestive intolerance to cow's milk (DM) is reviewed. This phenomenon is transient, starting during the first 3 months of life and, as a rule, disappearing after 2 yr. Total antimilk antibodies (AAM) and anti-β-lactoglobulin, α-lactalbumin, casein, serum albumin, and bovine α-globulins may be detected by passive hemagglutination and precipitation. Clinically, β-lactoglobulin is the most allergenic fraction, and AAM belongs to IgG and IgA in particular. Elevated AAM has also been detected in cases of nonspecific diarrhea and celiac disease. Further, antimilk IgE levels are also detectable in patients with DM, and a relation between the clinical symptomatology and allergy to cow's milk is not clear. Immunity to cellular mediation has also been implicated in DM. A positive lymphoblastic transformation test has been reported in DM, but it cannot exclude or confirm the presence of DM. Others have reported elevated IgA serum levels and IgA and IgM fecal levels in DM. Jejunal biopsy at the time of appearance of DM has revealed increased numbers of cells with IgA and IgM. Plasmacytes with IgE have also been reported in the lamina propria. In retrospect, DM is attributed to a disturbance of local or general immune reactions.

3255 REINVESTIGATION OF LACTOSE INTOLERANT CHILDREN: LACK OF CORRELATION BETWEEN CONTINUING LACTOSE INTOLERANCE AND SMALL INTESTINAL MORPHOLOGY, DISACCHARIDASE ACTIVITY, AND LACTOSE TOLERANCE TESTS. (Eng.) Harrison, M.; Walker-Smith, J. A. (Medical Coll. St. Bartholomew's Hosp., London, England). *Gut* 18(1):48-52; 1977.

Thirty children (aged 2-38 months) on a lactose-free diet who had previously been diagnosed as having secondary lactose intolerance were reinvestigated on 32 occasions by a p.o. lactose tolerance test, small intestinal biopsy, and measurement of disaccharidase activity to detect the presence of continuing lactose intolerance before reintroduction of milk. Four children developed profuse diarrhea, with 0.5-2% reducing substances in the stools and the pattern of lactose malabsorption on stool chromatography after a lactose tolerance test (LTT); a clinical diagnosis of continuing lactose intolerance was made in these children. There was no correlation between this clinical diagnosis, the maximum rise in blood glucose during the LTT, the morphology of the small intestinal mucosa, or the level of lactase activity. Clinical lactose intolerance occurred whether the rise in blood glucose was flat, border-line, or normal. Lactase activities were normal in all patients showing clinical lactose intolerance, and most children with a flat rise had normal lactase levels on biopsy. It is concluded that there is a negative correlation on the one hand between the maximum rise in blood glucose during LTT, the small intestinal morphology, and lactase activity, and on the other hand with continuing lactose intolerance.

3256 POLYMYOSITIS AS A CAUSE OF MALABSORPTION. A CASE REPORT. (Eng.) Transfeldt, E. E.; Morley, J. E.; Segal, F.; Klein, A.; Bill, P.; Fancourt, M. (Baragwanath Hosp., Johannesburg, South Africa). *S. Afr. Med. J.* 51(6):176-178; 1977.

The case report of a 52-yr-old woman with malabsorption associated with polymyositis is presented. The patient presented with fatigue, weight loss, weakness, dysphagia for solids, and chronic constipation. She showed evidence of malabsorption, with low serum levels of albumin, carotene, vitamin A, and iron. D-xylose absorption was indicative of malabsorption, and the glucose tolerance curve was flat. There was evidence of bacterial overgrowth in the duodenal aspirate, and *Giardia lamblia* was found in the stools. The esophagus was dilated and aperistaltic. The duodenum and jejunum were dilated, and small bowel transit time was prolonged. The muscle enzyme levels were elevated, and esophageal manometry and electromyography revealed features consistent with polymyositis. A duodenal biopsy specimen revealed a mild inflammatory cell infiltrate of the lamina propria and a decrease in elastic tissue. The patient responded to treatment with steroids, antibiotics, and metronidazole. The mechanism of malabsorption in polymyositis probably involves bacterial overgrowth in the small intestine, owing to impaired intestinal motility.

3257 JEJUNAL MUCOSA IN INFANTILE PROTEIN-CALORIE DEFICIENCY. (Eng.) Loeb, H.; Van Steirteghem, A.; Bossuyt, M.; Rodesch, P. (Kindergeneeskunde, Sint-Pieterziekenhuis, Hoogstraat 320, B-1000 Brussels, Belgium). *Acta Paediatr. Belg.* 29(1):19-23; 1976.

The jejunal mucosae were examined in 11 children, 1 to 12 yr of age, who had protein-calorie deficiencies with hypoproteinemia to determine whether the degree of villous atrophy has any relationship to the severity of the condition or length of treatment. Five of the children presented with kwashiorkor, six with marasmic kwashiorkor, and all but two of the children had had 2 to 17 weeks of refeeding. All the children had diarrhea during refeeding. Direct examination of the jejunal mucosae taken by intestinal biopsy showed mainly leaves and ridges, without any evidence of complete villous atrophy, characterized by a mosaic pattern. Histological examination revealed either normal mucosae or only minor atrophy in all but one child, who had generalized edema and subtotal atrophy and who had not yet received any treatment. However, the other child who had not received treatment had normal mucosae, while some children who had had 2 months of refeeding still showed minor atrophy. No apparent correlation could be drawn between the degree of villous atrophy, but the severity of hypoproteinemia, the duration of treatment, and the presence of diarrhea.

3258 WHIPPLE'S DISEASE WITH MINIMAL INTESTINAL INVOLVEMENT. (Eng.) Moorthy, S.; Nolley, G.; Hermos, J. A. (Boston Veterans Admin. Hosp., Boston, MA). *Gut* 18(2):152-155; 1977.

An uncharacteristic case of Whipple's disease occurring in a 46-yr-old man is presented. The patient presented with a 2-yr history of dementia. Supranuclear ophthalmoplegia, focal myoclonic seizures, fever, lymphadenopathy, panhypopituitarism, and arthritis of both knees were present. Biopsies of both the synovial membrane of the knee, and an axillary lymph node revealed clusters of PAS-positive macrophages. The patient appeared to be undernourished, but had neither diarrhea nor abdominal pain. Barium contrast examinations of the upper and lower gastrointestinal tract were normal, and there was no excess stool fat. The ultrastructural findings in two of four p.o. intestinal biopsies taken at the ligament of Treitz were normal. In the other two specimens, the mucosal architectures were normal in most sections. In one biopsy, however, a focus of macrophages containing PAS-positive material occurred in the lamina propria, and in the other biopsy, scattered PAS-positive macrophages were found at the base of the crypts. With antibiotic therapy, the patient became afebrile, and his arthritis and general physical condition showed objective improvement. His mental status improved moderately, but there were no significant changes in ophthalmoplegia and panhypopituitarism. Because the intestinal lesions of Whipple's disease may be minimal or patchy, rather than diffuse, multiple biopsies should be obtained.

LARGE INTESTINE

3272 CLINICAL FEATURE, TREATMENT AND PROGNOSIS OF CARCINOID TUMORS: PRELIMINARY OBSERVATIONS IN 14 PATIENTS. (Ger.) Brunner, H.; Kreig, H.; Bruning, K. W. (Chirurgische Klinik der Universitat, Langenbeckstrasse 1, D-6500 Mainz, W. Germany). *Med. Klin.* 72(8):295-299; 1977.

The clinical features, treatment, and prognosis of carcinoid tumors (CT) in 14 patients are presented. The tumor was localized in the appendix (7 patients), small intestine (3), duodenum (1), rectum (1), and lungs (2). Surgery revealed no true carcinoid syndrome in any of the patients, although widespread metastases were seen in two patients. The patients were followed up 6 months to 14 yr after surgery. Appendicitis was suspected in seven patients; one of whom underwent laparotomy because of an adhesion ileus. Histological examination revealed a noninvasive growing carcinoid and one carcinoid with tumor formation of the muscle layers. The CT had affected the appendix tip in six patients and the base in one patient. All patients remained tumor-free at follow-up. The three patients with CT of the small intestines presented uncharacteristic gastrointestinal symptoms; one had intestinal bleeding. At surgery, a stenosing neoplasm of the ileum with diffuse metastases of the liver and a smooth tumor of the cecum were seen in this patient. The other two patients underwent resection. However, two of the three died postoperatively of cardiorespiratory complications, and the third died suddenly of unknown reasons 8 weeks after operation. The rectal CT was seen in a 33-yr-old woman who had had bloody stools for 3 months. She had no recurrence after surgery. The patient with duodenal CT had adenocarcinoma, and she underwent a resection of the duodenum and pancreas head. A 45-yr-old patient with carcinoid CT and invasive growth was tumor-free 5 yr after lobectomy (LC). LC was also performed in a 16-yr-old girl with bronchial adenoma. The patient was without recurrence at 1-yr follow-up.

3273 HEXOSAMINE-CONTAINING MACROMOLECULES IN HUMAN COLON CARCINOMAS. (Eng.) Terho, T.; Laitio, M. (Dept. Physiology, Univ. Turku, Turku, Finland). *Scand. J. Gastroenterol.* 12(1):7-15; 1977.

Hexosamine-containing macromolecules from normal, transitional, and carcinomatous areas of five resected colons were isolated and characterized. The total concentration of these macromolecules was twice as high in carcinoma areas as in normal areas. While normal mucosa contained mainly sulphated mucin, transitional mucosa and carcinoma cells contained more nonsulphated acid mucin. Acid glycosaminoglycans increased from normal to transitional to carcinoma areas. The concentrations of high molecular weight glycopeptides did not vary in the different areas, but these glycopeptides were more highly sulphated in normal mucosa. Low molecular weight glycopeptides, which made up about half of all hexosamine-containing molecules, were four times as abundant in carcinoma areas and twice as abundant in transitional areas as in normal mucosa. It is suggested that the acid glycosaminoglycans may form a protective barrier around the tumor and, thus, prevent an immunological reaction against it.

3274 CHAGAS' DISEASE OF THE COLON. (Eng.) Da Silveira, G. M. (Federal Univ. Bahia, Bahia, Brazil). *Br. J. Surg.* 63(10):831-835; 1976.

The pre- and postoperative radiographic features, the surgical treatment, the incidence of complications, and the late results in 100 operated cases of chagasic megacolon are reported. The patients ranged in age from 22-76 yr. All patients underwent abdominoperineal rectosigmoidoscopy. The incidence of complications was higher in the 31 patients who underwent direct anastomosis than in those who underwent delayed anastomosis. Among the patients undergoing direct anastomosis, the complications included infection of the presacral space (19.3%), partial breakdown of anastomosis (12.9%), total breakdown of anastomosis (6.4%), stercoraceous fistula (6.4%), vesicorectal fistula (3.2%), peritonitis (3.2%), stenosis of anastomosis (12.9%), and hemorrhage (3.2%). Among those that underwent delayed anastomosis, the corresponding values were 8.6%, 8.6%, 0%, 2.8%, 0%, 0%, 4.3%, and 0%; other complications among these patients included necrosis with retraction of pull-through (4.3%) and nonstenotic narrowing (14.4%). The mortality rate among the patients who underwent the direct procedure was 9.6%, while that in the delayed anastomosis patients was 1.4%. All of the 12 patients who were followed up had normal bowel function. Abdominoperineal rectosigmoidectomy with delayed anastomosis is the recommended surgical treatment for chagasic megacolon.

3275 PERSISTENCE OF PROCTITIS IN 2 CASES OF CLINDAMYCIN-ASSOCIATED COLITIS. (Eng.) Goodacre, R. L.; Hamilton, J. D.; Mullens, J. E.; Qizilbash, A. (McMaster Univ. Medical Center, 1200 Main St. West, Hamilton, Ontario L8S 4J9, Canada). *Gastroenterology* 72(1):149-152; 1977.

Two cases of persisting proctitis after an episode of clindamycin-associated colitis are presented. The first patient, a 33-yr-old woman, received an 8-day course of clindamycin (150 mg, 3 x) followed by another 8-day course 6 months later. The second patient, a 64-yr-old woman, received clindamycin (150 mg, 4 x) daily for 22 days prior to hospitalization for symptoms of colitis. Both patients presented with diarrhea associated with mucus and blood. Sigmoidoscopy and rectal biopsy did not reveal a typical pseudomembrane in either patient. Both patients received short courses of Lomotil. The diagnosis of pseudomembranous colitis was not made in either patient until subtotal colectomy was carried out. In both patients, the resected specimen showed persistent mucosal inflammation and fibrosis of the submucosa and muscular layer. The arteries were also narrowed, but no complete occlusion of the vessels was present. Severe proctitis persisted in the rectal stumps of both patients until their removal. The severity of the colitis may have been attributable to the repetition of the course of clindamycin in the first patient and to its prolongation in the second. Lomotil may have contributed to the deterioration seen in both patients, leading to colectomy.

3276 PSEUDOMEMBRANOUS COLITIS. (Eng.) Price, A. B.; Davies, D. R. (Dept. Histopathology, Northwick Park Hosp. and CRC, Harrow, Middlesex, England). *J. Clin. Pathol.* 30(1):1-12; 1977.

A study of 29 patients with pseudomembranous colitis defined the histopathological criteria, based on rectal biopsy material, necessary for diagnosis of three basic stages of the disease. Characteristics that facilitate the differential diagnosis of pseudomembranous colitis from nondiagnostic proctitis in the milder stages to acute ischemic colitis are discussed. Pseudomembranous colitis is characterized by the presence of yellow plaques, 0.2 to 2.0 cm in diameter, which result from localized necrosis of the mucosa in the colon. As the disease progresses, deeper layers of the mucosae are affected, and all normal mucosae between the plaques disappear. The polymorph is the main inflammatory cell type and is associated with nuclear debris. The appearance of the colitis was associated with pre-existing disease in 28 patients and with recent antibiotic therapy in 27 of the 29 patients. A record of previous disease and medications may be useful in diagnosing pseudomembranous colitis. This association of pseudomembranous colitis with previous disease and antibiotic therapy may induce local mucosal damage, which may trigger the Schwartzman reaction. Capillary microthrombosis may then lead to the mucosal necrosis seen later in the disease.

3277 TUBERCULOUS COLITIS. (Eng.) Balikian, J. P.; Uthman, S. M.; Kabakian, H. A. (American Univ. Medical Center, Beirut, Lebanon). *Am. J. Proctol.* 28(1):75-79; 1977.

The case of a 45-yr-old woman with extensive tuberculous colitis is presented, and the differential diagnosis is discussed. The patient had a history of abdominal pain (18 yr), secondary sterility, increasing anorexia, weight loss, and intestinal obstruction. She had mild hepatosplenomegaly and bloody diarrhea. Unusual features included the absence of clinical and radiological evidence of pulmonary tuberculosis and extensive right-sided colitis with little involvement of the terminal ileum. Roentgenograms showed diffuse ulceration and loss of haustrations, thickening and shortening of the bowel, and stricture formation. Skip lesions involved the right colon, the sigmoid colon, and several small bowel segments. The patient responded to anti-tuberculous therapy.

3278 TRANSCATHETER EMBOLIZATION FOR TREATMENT OF DIVERTICULAR HEMORRHAGE. (Eng.) Goldberger, L. E.; Bookstein, J. J. (Univ. California Medical Center at San Diego, 225 W. Dickinson St., San Diego, CA 92103). *Radiology* 122(3):613-617; 1977.

The cases of two patients with massive diverticular bleeding that responded favorably to selective transcatheter embolization are presented, and the technique is described. After initial catheterization and angiography of the superior mesenteric artery, a J-shaped guidewire is advanced as far as possible, usually into a distal ileal or ileo-colic artery. A thin-walled catheter shaped to correspond to the forward bend from the aorta into the superior mesenteric artery, with a 45-degree curve at the distal 1 cm, is advanced over a guidewire to a very distal branch, after which the wire is withdrawn. The catheter is then slowly retracted, progressively engaging each branch along the aspect toward which it is pointed. When the desired branch is encountered, a slight forward thrust enables the placement of the catheter. This technique stopped the bleeding in a 52-yr-old man with diverticular bleeding from a distal branch of the right colic artery. In the second patient, a 69-yr-old man, selective mesenteric angiography revealed bleeding from the right colic artery, which ceased after embolization with oxidized cellulose. Ten months later, the same procedure revealed bleeding from the left side of the transverse colon; partial colectomy with right-sided colostomy and left-sided mucous fistula was performed. The bleeding in both patients had failed to respond to vasopressin infusion. Transcatheter embolization is proposed as an alternative to surgical intervention.

3279 TREATMENT OF SYMPTOMATIC DIVERTICULAR DISEASE WITH A HIGH-FIBRE DIET. (Eng.) Brodribb, A. J. M. (Radcliffe Infirmary, Oxford OX2 6HE, England). *Lancet* 1(8013):664-666; 1977.

The therapeutic value of increasing the daily dietary fiber intake was assessed over 3 months in a double-blind controlled trial of 18 patients with diverticula disease. The patients took either bran or wheat (control) crispbread, amounting to 6.7 g and 0.6 g of dietary fiber, resp., daily. The patients completed a detailed symptomatic questionnaire on dyspeptic symptoms, pain, and symptoms of bowel dysfunction before and after treatment, and the symptoms were scored 0-6 for frequency and severity. There was a highly significant difference in the reduction of total symptom score (high fiber, from 34.3 to 8.1; control from 42.0 to 35.1; p<0.002). The difference in the reduction of pain score was significant (high fiber, from 11.1 to 1.1; control from 12.7 to 10.2; p<0.02), although dyspeptic and bowel dysfunction score differences did not reach statistically significant levels. Two of the nine control patients required further treatment, whil none of the patients on the high fiber diet did. The results demonstrate the therapeutic value of increasin fiber intake in patients with diverticular disease.

3280 EMERGENCE OF DIVERTICULAR DISEASE IN THE URBAN SOUTH AFRICAN BLACK. (Eng.) Segal, I.; Solomon, A.; Hunt, J. A. (Baragwanath Hosp., P.O. Bertsham, 2013, Johannesburg, South Africa). *Gastroenterology* 72(2):215-219; 1977.

The first 16 African black patients seen at Baragwanath Hospital with diverticular disease provided an opportunity to study the effects of urbanization on disease patterns. The mean age of the patients was 48.9 yr, and all had lived in an urban environment for over 20 yr. Most patients had been eating a refined food-low fiber diet since childhood. Half of the patients did not eat maize meal (the staple food of rural blacks), and the other half ate only refined white maize meal. Six patients presented with rectal bleeding, and four presented with hemorrhoids; all 16 patients had a history of constipation. Because of the previous rarity of diverticular disease in black Africans, it was not suspected at presentation. Barium enema studies revealed 6 patients with isolated diverticula (i.e., no more than three per region), and the remaining 10 had diffuse diverticula, the type usually seen in Western countries. Half of the patients had diverticula of over 5 mm. The patients' dietary history confirms the hypothesis that a low fiber diet contributes to diverticular disease, and also shows that the urbanization of the South African black has been accompanied by the emergence of diverticular disease, a condition hitherto virtually nonexistent in this population.

3281 EVIDENCE THAT ABNORMAL MYOELECTRICAL ACTIVITY PRODUCES COLONIC MOTOR DYSFUNCTION IN THE IRRITABLE BOWEL SYNDROME. (Eng.) Snape, W. J., Jr.; Carlson, G. M.; Matarazzo, S. A.; Cohen, S. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Gastroenterology* 72(3):383-387; 1977.

The relationship of altered slow-wave activity and the abnormal motility of the distal colon seen in patients with the irritable bowel syndrome was studied in 20 patients and 12 controls. Myoelectrical activity was recorded using a bipolar electrode clipped to the distal colonic mucosa, and motor activity was measured by perfused catheters. Colonic slow waves and contractions were present at two frequencies, 6 and 3 cycles/min. The slow wave frequency seemed to determine the frequency of colonic motor activity. Patients with the irritable bowel syndrome had increased 3-cycle/min slow wave activity in the basal state (comprising 39.6 ± 4.2% of total slow-wave activity versus 9.9 ± 2.2% in controls ($p<0.001$). However, no difference in basal 3-cycle/min motor activity was present between the two groups ($p>0.05$). When colonic motor activity was increased with i.v. cholecystokinin (1.0 U/kg) or pentagastrin (0.5 μg/kg), patients with irritable bowel syndrome showed a marked increase in 3-cycle/min contractile activity, occurring simultaneously with 3-cycle/min slow wave activity. These studies suggest that increased colonic 3-cycle/min slow wave activity in patients with the irritable bowel syndrome may be the basic abnormality that leads to colonic motor dysfunction in response to various physiological stimuli.

3282 COLONIC OBSTRUCTION BY GIANT PSEUDOPOLYPOSIS. (Eng.) Fitterer, J. D.; Cromwell, L. G.; Sims, J. E. (Sacred Heart Medical Center, Spokane, WA 99204). *Gastroenterology* 72(1):153-156; 1977.

The case of a 38-yr-old woman with obstructing giant pseudopolyposis of the descending colon is described. The patient had a 16-yr history of ulcerative colitis, and recurrent episodes of hematochezia were treated successfully with salicylazosulfapyridine. When the patient presented with crampy left lower abdominal pain and hematochezia that did not respond to treatment, proctoscopy revealed severe ulcerative changes and several small pseudopolyps. A barium examination showed a mass completely obstructing retrograde flow of barium at the level of the lower descending colon, and colonoscopy revealed that the mass was at the junction of the descending and sigmoid colons; the mass was lobulated and appeared to be a polypoid carcinoma. A total colectomy and ileostomy was performed. Sections through the main mass revealed it to be a group of confluent sessile to polypoid inflammatory masses consisting of hyperplastic colonic epithelium with focal acute undermined ulcers and crypt abscesses scattered throughout its surfaces. The epithelium in general was well oriented on redundant folds of lamina propria containing aggregates of chronic inflammatory cells, in some areas with germinal center formation. Undermining mucosal ulceration occurred in a well localized circumferential band of colonic mucosa immediately proximal and distal to the mass. The inflammatory infiltrate was limited to the mucosa. No granulomas, hyperplasia of the muscularis propria, serosal inflammation, or neoplastic epithelium was identified. Since carcinoma of the colon has never been reported to arise in inflammatory polyps, the authors conclude that surgery in nonobstructed patients with giant pseudopolyposis may not be necessary.

LARGE INTESTINE

Ulcerative Colitis

3317 ZINC IN ULCERATIVE COLITIS: A THERAPEUTIC TRIAL AND REPORT ON PLASMA LEVELS. (Eng.) Dronfield, M. W.; Malone, J. D. G.; Langman, M. J. S. (City Hosp., Nottingham, England). *Gut* 18(1):33-36; 1977.

A double-blind controlled trial of p.o. zinc sulphate as adjuvant treatment in idiopathic ulcerative colitis or proctitis in relapse was undertaken in 51 patients. Twenty-six patients received zinc (220 mg zinc sulphate t.i.d. for 4 weeks), and the remainder received placebo. The patients were all receiving other medications for their disease (sulphasalazine or prednisolone). Although 46.2% of those receiving zinc showed clinical improvement by six points or more and only 32% of the controls showed similar improvement, this was not statistically significant. Sigmoidoscopy showed no significant improvement in the zinc-treated patients in comparison to the controls. No difference was found between plasma zinc levels in an additional 46 patients with idiopathic ulcerative colitis or proctitis and those obtained in healthy controls. Oral zinc sulphate is of no benefit as an adjuvant to already established treatment in the management of relapse of ulcerative colitis.

3318 REGIONAL INTESTINAL BLOOD FLOW IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Hulten, L.; Lindhagen, J.; Lundgren, O.; Fasth, S.; Ahren, C. (Dept. Surgery II, Univ. Goteborg, Goteborg, Sweden). *Gastroenterology* 72(3):388-396; 1977.

Using a recently developed isotope washout technique, regional intestinal blood flow and its intramural distribution were determined during surgery and were correlated with the morphological inflammatory and vascular features of ulcerative colitis (UC) and Crohn's disease (CD) at different stages and locations. In patients with severe UC and CD, the total blood flow was significantly increased to 64 ± 9 ml/min x 100 g, n=13; the mucosal-submucosal blood flow ammounted to 121 ± 25 ml/min x 100 g, n=7. The muscularis blood flow was within normal range (18 ± 10, n=7). In chronic, long-standing quiescent or inactive UC, in "healed colitis," and in chronic segmental colitis (CD), colonic blood flow was normal or even reduced (13 ± 2 ml/min, n=8); the decrease in flow comprised both the mucosa-submucosa (21 ± 3 ml/min, n=3) and the muscularis (7 ± 3 ml/min, n=3). In the early exudative stage of CD in the ileum, the total blood flow was normal (26 ± 5 ml/min, n=7), with a normal mucosal-submucosal blood flow (35 ± 5 ml/min, n=3). In the late fibrosing stage, total blood flow was reduced (11 ± 1 ml/min, n=6) as was the mucosal-submucosal flow (10 ± 4 ml/min, n=3). The muscularis blood flow was reduced in both these stages of ileal CD (7 ± 1 ml/min, n=6). There was a satisfactory agreement between the obtained blood flow figures and the morphologically observed vascular pattern.

3319 ERYTHEMA MULTIFORME IN ASSOCIATION WITH ACTIVE ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Chapman, R. S.; Forsyth, A.; MacQueen, A. (Stobhill General Hosp., Glasgow, G21 3UW, Scotland). *Dermatologica* 154(1):32-38; 1977.

The case reports of a patient with ulcerative colitis and a patient with Crohn's disease of the anal canal and rectum who both developed predominantly vesiculobullous skin reactions are presented. In both cases, the skin eruption appeared during an active phase of the bowel disorder and resolved as the disease was controlled. In each patient, the skin changes formed part of a symptom complex including pyrexia and oral or genital ulceration. In the first patient, a 41-yr-old woman with ulcerative colitis, arthropathy was present. The skin lesions continued to appear until systemic steroid therapy was commenced 4 weeks after the onset of bowel and skin symptoms. Total colectomy was eventually required, and the skin lesions did not recur postoperatively. In the second patient, a 49-yr-old woman with a 5-yr history of proctitis, Crohn's disease was diagnosed after an exacerbation of symptoms and the appearance of erythematous macules. A skin biopsy from a typical lesion revealed a normal epidermis, marked dermal edema, and moderately heavy focal aggregates of inflammatory cells. The patient was treated with analgesics, antacids, and salicylazosulfapyridine; the skin lesions cleared 50 days after their onset, and there have been no recurrences. The authors suggest that erythema multiforme should be accepted as a skin reaction associated with inflammatory large bowel disorder.

3320 THE ROLE OF COLONOSCOPY IN THE DIFFERENTIAL DIAGNOSIS OF INFLAMMATORY BOWEL DISEASE. (Eng.) Waye, J. D. (1065 Park Ave., New York, NY 10028). *Gastrointest. Endosc.* 23(3):150-154; 1977.

Guidelines for the use of colonoscopy in the differential diagnosis of ulcerative and granulomatous colitis are discussed. The most important application of colonoscopy in inflammatory bowel disease is in the evaluation of strictures, in the identification of pseudopolyps and their differentiation from carcinoma, in the preoperative evaluation of patients with granulomatous bowel disease, and in the evaluation of filling defects seen on barium enema examination. Thus, colonoscopy should not be carried out in all patients with inflammatory bowel disease, and it is contraindicated in a patient at the onset of acute severe ulcerative colitis.

3321 T AND B LYMPHOCYTES AND CUTANEOUS ANERGY IN INFLAMMATORY BOWEL DISEASE. (Eng.) Sachar, D. B.; Taub, R. N.; Ramachandar, K.; Meyers, S.; Forman, S. P.; Douglas, S. D.; Janowitz, H. D. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Ann. N.Y. Acad. Sci.* 278:565-573; 1976.

The cellular immune status of patients with inflammatory bowel disease (IBD, both Crohn's disease and ulcerative colitis) is reported. The patients were divided into four groups: group 1 (33 patients) was taking salicylazosulfapyridine; group 2 (21 patients) was receiving steroid therapy (oral prednisone, 10-40 mg/day); group 3 (3 patients) was receiving immunosuppressive therapy (azathioprine 100-150 mg/day); and group 4 (15 patients) served as normal controls. A significant depression of mean T lymphocyte ($p<0.005$) and mean absolute T lymphocyte counts ($p<0.006$) was seen in all of the IBD groups. A corresponding increase in B lymphocytes ($p<0.025$) was found among all but the azathioprine-treated group. In the azathioprine-treated group, B cell proportions and absolute counts were depressed to control levels (13 ± 5%, 230 ± 100 cells/mm^3). No correlation was reported between lymphocyte values and extent of the disease. A high incidence of anergy upon skin testing with 2,4-dinitrochlorobenzene (DNCB) among IBD patients is reported. However, no relationship between DNCB responses and T lymphocyte levels in individual patients was shown. Research on the therapeutic response of azathioprine and further clarification of cellular immune status in IBD patients are suggested.

3322 USE OF NEROBOL AND MEXASE IN COMBINATION WITH MINERAL WATER OF THE MORSHIN HEALTH RESORT IN PATIENTS WITH CHRONIC COLITIS. (Rus.) Datsun, T. A. (Ivano-Frankovsk Medical Inst., Ivano-Frankovsk, USSR). *Vrach. Delo* (6):78-82; 1976.

PANCREAS

3325 PANCREATIC ASCITES: DIAGNOSIS OF LEAKAGE SITE BY ENDOSCOPIC PANCREATOGRAPHY.

(Eng.) Rawlings, W.; Bynum, T. E.; Pasternak, G. (Johns Hopkins Univ. Sch. Medicine, Baltimore, MD 21205). *Surgery* 81(3):363-365; 1977.

The case of a patient with pancreatic ascites in whom preoperative demonstration of pancreatic anatomy by endoscopic pancreatography facilitated surgical repair of the leak is presented. The patient presented with ascites, hyperamylasemia, a history of weight loss, and crampy lower abdominal pain; a diagnosis of subacute and chronic pancreatitis was made. He was treated conservatively with parenteral alimentation, bed rest, and nasogastric suction, and the ascites were drained on two occasions. The ascites continued to reaccumulate. Endoscopic pancreatography revealed a 3 x 3 cm pseudocyst in the distal third of the pancreatic duct. X-ray films taken within the first 10 min demonstrated escape of the contrast media into the peritoneal cavity. The presence of pseudocyst was confirmed at surgery, and a distal pancreatectomy were performed. The patient's serum amylase decreased, and there was no reaccumulation of ascites. The authors suggest that endoscopic pancreatography should be done early in the clinical course of most patients with pancreatic ascites, since the information obtained can facilitate medical and surgical management.

3326 ACINAR CELL NEOPLASMS OF THE EXOCRINE PANCREAS.

(Eng.) Webb, J. N. (Western General Hosp., Edinburgh, Scotland). *J. Clin. Pathol.* 30(2):103-112; 1977.

An examination of 105 carcinomas of the exocrine pancreas revealed 12 acinar cell neoplasms, including 7 acinar cell carcinomas, 4 mixed acinar and ductal carcinomas, and 1 acinar cell adenoma. Histological and ultrastructural appearances of cells typical of these neoplasms are described. The features distinguishing acinar adenocarcinomas from the more common ductal adenocarcinomas, as well as undifferentiated carcinomas, islet cell carcinomas, oat cell carcinomas, and carcinoid tumors are discussed. The occurrence of thrombotic endocarditis in 3 of the 11 carcinomas suggest the presence of widespread fat necrosis, which has been previously noted in association with these carcinomas. The extreme malignancy of pancreatic carcinomas is stressed. Accurate histological classification of these carcinomas may be important in future epidemiological studies.

3327 THE PANCREATIC INVOLVEMENT IN DISSEMINATED "COLLAGEN" DISORDERS. STUDIES OF PANCREATIC SECRETION IN PATIENTS WITH SCLERODERMA AND SJOGREN'S "DISEASE."

(Eng.) Dreiling, D. A.; Soto, J. M. (Mt. Sinai Sch. Medicine, City Univ. New York, 100th St. & Fifth Ave., New York, NY 10029). *Am. J. Gastroenterol.* 66(6):546-553; 1976.

A study was made of 66 patients with Sjogren's disease and/or scleroderma to elucidate the relationship between pancreatic secretory patterns, pathological factors, and digestive complaints associated with these collagen disorders. Either pancreatic insufficiency or hypersecretion was observed in 17 of 23 patients with Sjogren's disease, 19 of 31 patients with scleroderma, and 4 patients with both Sjogren's disease and scleroderma. All of these patients suffered from digestive complaints, such as dysphagia, constipation, and diarrhea with or without steatorrhea. Abnormal gastric secretion and/or biliary flow were also frequently observed. Systemic complaints in Sjogren's disease may result from any of the following pathological factors: lupus erythematosus, Raynaud's syndrome, dermatomyositis, lymphoma, avitaminoses, and rheumatoid arthritis. However, the syndrome is most often characterized by arteritis, intestinal fibrosis, and main ductular sclerosis of the pancreas. On the other hand, digestive complaints associated with scleroderma are often due to a more widespread pathology involving many organs of the digestive system, as well as the skin and other organs, resulting from inflammatory exudates, fibrosis, arteritis, and autoimmune reactions. Therefore, diarrhea in Sjogren's disease can be readily attributed to pancreatic dysfunction, but a more complex pathology must be considered in the case of scleroderma. Since 19 of the 23 patients with Sjogren's disease, 24 of the 31 patients with scleroderma, and 3 of the 4 patients with the combined disorders had received either antibiotics, antimetabolites, and/or steroids, drug therapy is probably partially responsible for certain of these dysfunctions. However, similar dysfunctions were exhibited among a small group of patients with either Sjogren's disease or scleroderma who had received no medication. Therefore, an exact knowledge and specific treatment of all pathogenetic factors involved in each patient's particular condition would greatly improve treatment of generalized gastrointestinal syndromes.

3328 FUSION ANOMALIES OF THE PANCREATIC DUCTAL SYSTEM: DIFFERENTIATION FROM PATHOLOGIC STATES. (Eng.) Belber, J. P.; Bill, K. (Veterans Admin. Hosp., 150 Muir Rd., Martinez, CA 94553). *Radiology* 122(3):637-642; 1977.

Comparisons were made of overall ductal contour, branching pattern, and ductal diameter in the pancreatograms of 195 patients to identify those characteristics that might clearly differentiate fusion anomalies from pathologic changes due to pancreatitis or malignancy. Seven cases were thought to represent pathologic obstruction, and eight were considered to be isolated ventral pancreatic ducts. Opacification of the parenchyma with minimal injection of contrast material occurred in seven of eight cases without any subsequent evidence of pancreatitis. On the basis of results obtained in the present study and in previous studies, the following conclusions were made. If fusion of the ventral and dorsal pancreatic ducts does not occur during fetal life, endoscopic retrograde cannulation of the papilla of Vater will visualize a small complete ductal system that is confined to the head of the pancreas. This system is characterized by normal arborizations throughout, relatively small duct diameters and the absence of a communication with the minor papilla. In contrast, if fusion has taken place and the ductal system is shortened by disease, pancreatography will demonstrate abrupt proximal termination or proximal tapering without side branches and may show a significant duct of Santorini. If the ducts have fused, an area of narrowing approximately 3-20 mm in length commonly occurs at the level of fusion. This should not be confused with pathologic ductal stenosis.

3329 BLOOD DIFFUSION OF PANCREATIC LIPASE FOLLOWING ENDOSCOPIC PANCREATOGRAPHY ASSOCIATED WITH NEPHROGRAPHY: EVIDENCE FOR ACINO PORTAL PATHWAYS IN MAN [Abstract]. (Eng.) Figarella, C.; Sahel, J.; Oi, I.; Sarles, H. (INSERM, 46 Chemin de la Gaye, 13009 Marseille, France). *Scand. J. Gastroenterol.* 11(41):41; 1976.

PANCREAS

Pancreatitis

336 ERYTHEMA Ab Igne, A SIGN OF PANCREATIC DISEASE. (Eng.) Butler, M. L. (Letterman rmy Medical Center, Presidio of San Francisco, San rancisco, CA 94129). *Am. J. Gastroenterol.* 67(1): 7-79; 1977.

he cases of four patients with pancreatitis and one atient with pancreatic carcinoma in whom erythema *b igne* resulting from the application of heat are resented. All patients had used a heating pad or ot water bottle on their abdomens or lower backs to elieve chronic abdominal discomfort. Two pancreaitis patients were alcoholics, one had acute choleystitis, and the fourth had no previous illness. he presence of erythema *ab igne* is a sign of oranicity, which should lead to an investigation of he pancreas as the source of the patient's pain.

337 PANCREATITIS--A RETROSPECTIVE STUDY. (Eng.) Read, G.; Braganza, J. M.; Howat, H. T. Manchester Royal Infirmary, Manchester, England). *ut* 17(12):945-952; 1976.

retrospective study of 119 patients with exocrine ancreatic disease was made to determine the factors ritical for an accurate prognosis of acute pancreatitis. The mortality and morbidity rates among atients with acute pancreatitis were much higher han among patients with relapsing acute pancreatitis r chronic pancreatitis. Acute pancreatitis afected a significantly older age group ($p<0.02$) than elapsing acute pancreatitis, the mean ages being 5.6 ± 15.7 and 44.3 ± 18.4 yr, resp. Gallstones nd extreme alcoholic intoxication were frequent tiological factors associated with relapsing acute ancreatitis, and chronic alcoholism was most comonly associated with chronic pancreatitis. No ingle clinical factor could be clearly associated ith acute pancreatitis. Pain and raised serum mylase levels were common, but not reliable sympoms of acute pancreatitis, while chronic pancreatiis was frequently associated with pain, permanent ancreatic insufficiency, steatorrhea, and diabetes, r intraductal pancreatic calculi.

338 GALLSTONE PANCREATITIS: PATHOPHYSIOLOGY. (Eng.) Kelly, T. R. (Akron City Hosp., kron, OH 44309). *Surgery* 80(4):488-492; 1976.

he stools of 45 patients with proven gallstone panreatitis were screened for gallstones. Forty-five atients with gallstones, but without pancreatitis, erved as controls. Gallstones were found in the tools of 38 of the 45 patients (84%) with gallstone ancreatitis and in only five (11%) controls. The atients with gallstone pancreatitis experienced a elief of symptoms and decreased serum amylase and ilirubin levels prior to rectal passage of the stones. perative cholangiography revealed reflux of contrast aterial into the pancreatic duct of 67% of the paients with gallstone pancreatitis and only of 18% of he controls. Of 38 patients that passed stones, 30 0 holangiograms (79%) demonstrated a functioning common channel. It appears that a functioning common channel is necessary for reflux and also favors stone passage. This study suggests that the pathophysiology of gallstone pancreatitis relates to the temporary impaction of migrating stones at the ampulla of Vater.

3339 PARACETAMOL-INDUCED ACUTE PANCREATITIS. (Eng.) Gilmore, I. T.; Tourvas, E. (St. Thomas's Hosp., London SE1 7EH, England). *Br. Med. J.* 1(6063):753-754; 1977.

The case of a patient in whom acute pancreatitis was induced by a paracetamol overdose is presented. The patient, a 31-yr-old woman with a 3-yr history of alcohol abuse, had taken 60 g of paracetamol 54 hr before she was hospitalized with severe upper abdominal pain and vomiting that lasted for 36 hr. The serum amylase level was 1,440 IU/1. The bilirubin level was 102 μM (6.0 mg/100 ml), and the alkaline phosphatase level was 10 King-Armstrong U/1. She had acute renal failure, requiring peritoneal dialysis. After 3 weeks in the hospital, her renal function returned to normal, but she had persistent abdominal tenderness, ileus, and fever. At laparotomy, 2 1 of cloudy bloodstained peritoneal fluid was found. The pancreas was edematous and hemorrhagic, with areas of fat necrosis. The liver was smooth and noncirrhotic. The patient recovered after 4 months of hospitalization.

3340 PANCREATITIS AND RENAL DISEASE. (Eng.) Robinson, D. O.; Alp, M. H.; Grant, A. K.; Lawrence, J. R. (Queen Elizabeth Hosp., Woodville Rd., Woodville, South Australia 5011). *Scand. J. Gastroenterol.* 12(1):17-20; 1977.

To study the etiology of acute pancreatitis occurring after renal transplantation, the case records of 168 renal transplant patients were surveyed; also the records of nontransplanted patients with classic renal failure who developed pancreatitis were studied. Five renal transplant patients with pancreatitis and four nontransplanted patients with pancreatitis and chronic renal failure were studied. The diagnosis of pancreatitis was established on clinical grounds and on a serum amylase level of >900 IU/1. Similar serum amylase elevation was not found in patients with chronic renal failure alone. The five transplant patients with pancreatitis were from a population of 168 renal transplant patients (3%). All five patients were being treated with prednisone and azathioprine. Among the four patients with pancreatitis and renal failure caused by polycystic kidneys, chronic pyelonephritis, or chronic glomerulonephritis, none had received immunosuppressive agents, but two were receiving regular furosemide therapy. One patient was on maintenance hemodialysis. Heavy alcohol ingestion, biliary tract disease, hyperlipidemia, and hypercalcemia were not found in any patient in either group. Three renal transplant patients with pancreatitis died, whereas all four patients with chronic renal failure survived. Although hypercalcemia and primary hyperparathyroidism were not found in the transplant and nontransplant subjects, elevated serum parathormone levels have been previously described in uremic patients with normocalcemia. This may be a factor in the development of pancreatitis in nontransplanted uremic patients.

3341 COXSACKIE AND MUMPSVIRUS INFECTION IN A PROSPECTIVE STUDY OF ACUTE PANCREATITIS.

(Eng.) Imrie, C. W.; Ferguson, J. C.; Sommerville, R. G. (Glasgow Royal Infirmary, Glasgow, Scotland). *Gut* 18(1):53-56; 1977.

To investigate the small group of patients with "idiopathic" pancreatitis and the role of virus infection in acute pancreatitis, routine screening for viral antibodies was undertaken in 116 patients. Five patients (all female) exhibited significant rising antibody titers to Coxsackie B or mumpsvirus, while none of the remaining 111 patients did; two patients had antibody titers to mumpsvirus and two patients had antibody titers to Coxsackie B viruses types B3, 4, or 5. One patient had positive titers to mumps V and Coxsackie B5. Evidence of biliary disease was present in two of the five patients, and none of the five had any evidence of excess alcohol intake, hyperlipoproteinemia, hyperparathyroidism, or other known etiological factors. Diarrhea was a prodromal feature of the pancreatitis in the five patients with evidence of viral disease. The incidence of pancreatitis without apparent cause among the 116 patients was 5.2%. Screening of patients with acute pancreatitis for Coxsackie B and mumpsvirus infections is worthwhile in the identification of etiological factors and may minimize protracted biliary investigations.

3342 SUBCLINICAL CHRONIC PANCREATITIS IN TYPE I HYPERLIPOPROTEINEMIA.

(Eng.) Krauss, R. M.; Levy, A. G. (Donner Lab., Univ. California, Berkeley, CA 94720). *Am. J. Med.* 62(1):144-149; 1977.

A case of severe pancreatic exocrine insufficiency in a 41-yr-old man with familial type I hyperlipoproteinemia (fat-induced hyperlipemia) is described. Plasma triglyceride concentration failed to increase significantly with increased dietary fat intake, and fecal fat excretion was markedly increased (72.7-89.5 g/day). Indices of intestinal function were normal. Pancreatic enzyme therapy resulted in reduced fat excretion and increased plasma triglyceride concentration. Secretin stimulation tests revealed impaired duodenal fluid volume and bicarbonate and pancreatic enzyme responses. Insulin-dependent diabetes mellitus had been diagnosed 3-yr earlier. No attacks of acute pancreatitis had occurred in the preceding 20 yr, and pancreatic damage may have resulted from repeated subclinical pancreatic insults due to elevated plasma lipid levels. This report is the first to indicate that pancreatic exocrine insufficiency may occur as a late complication of hyperlipemic disorders in the absence of recurrent acute pancreatitis. Steatorrhea may not be apparent because of therapeutic restriction of dietary fat, and the first manifestation of pancreatic exocrine disease may be an amelioration of fat-induced hyperlipemia.

3343 MECHANISM OF INCREASED RENAL CLEARANCE OF AMYLASE/CREATININE IN ACUTE PANCREATITIS.

(Eng.) Johnson, S. G.; Ellis, C. J.; Levitt, M. D. (Univ. Minnesota Hosp., Minneapolis, MN 55455). *N. Engl. J. Med.* 295(22):1214-1217; 1976.

Three possible causes of the increased ratio of amylase/creatinine clearance observed in acute pancreatitis were investigated in 10 patients with acute pancreatitis and in 20 controls. The presence of rapidly cleared isoamylase was excluded by studies of serum and urine, which demonstrated no anomalous isoamylases. In the patients with pancreatitis, the mean ratios of both pancreatic isoamylase (9.2 ± 0.6%) and salivary isoamylase (8.6 ± 1.6%) were significantly ($p <$ 0.01) elevated over the control values (2.4 ± 0.2 and 1.8 ± 0.2%, resp.). Increased glomerular permeability to amylase was excluded by the demonstration of normal renal clearance of dextrans. Tubular reabsorption of protein was tested by measuring the renal clearance of β_2-microglobulin. During acute pancreatitis, the ratio of the renal clearance of β_2-microglobulin to that of creatinine was 1.22 ± 0.52%, an 80-fold increase over normal values (0.015 ± 0.002%); there was a rapid return toward normal during convalescence. Presumably, this reversible renal tubular defect also reduces amylase reabsorption and accounts for the elevated renal clearance of amylase/creatinine observed in acute pancreatitis.

3344 THE USEFULNESS OF STOOL SCREENING FOR DIAGNOSING CHOLELITHIASIS IN ACUTE PANCREATITIS. A DESCRIPTION OF THE TECHNIQUE.

(Eng.) Acosta, J. M.; Rossi, R.; Ledesma, C. L. (Pte. Roca 786, 1er. Piso, Rosario, Argentina). *Am. J. Dig. Dis.* 22(2):168-172; 1977.

A detailed description of the technique employed for stool screening for gallstones in patients with pancreatitis is presented. The procedure was applied in 51 patients recovering from an attack of gallstone pancreatitis, in 51 control patients with known gallstones disease but without acute pancreatitis, and in 10 patients with acute alcoholic pancreatitis. Gallstones were found in the feces in 47 of the 51 patients with gallstone pancreatitis (92.1%), in only 6 of the 51 control cases (11.8%, $p<0.0001$), and in none of the 10 patients with alcoholic pancreatitis. In the group with gallstone pancreatitis, the finding occurred within 10 days of the attack. Oral cholecystography was also accomplished an average of 12.7 days after the attack in 38 of the 61 pancreatitis patients (28 with biliary and 10 with alcoholic pancreatitis). In 27 of the 28 patients with gallstone pancreatitis (96.4%) and in 4 of the 10 patients with alcoholic pancreatitis, radiologic evidence of cholelithiasis was found. There were 19 patients with gallstone pancreatitis who did not have a cholecystogram because of jaundice, recurrent pancreatitis, previous cholecystectomy, or pregnancy. These results suggest that stool screening is as accurate and reliable as cholecystography for the diagnosis of gallstones in individuals with pancreatitis. In addition, there are no contraindications, the method requires no special equipment or personnel, and it can be used much earlier than cholecystography in patients recovering from an attack of acute pancreatitis.

3359 QUANTITATIVE ASPECTS OF THE CONVERSION OF 5β-CHOLESTANE INTERMEDIATES TO BILE ACIDS IN MAN. (Eng.) Schwartz, C. C.; Cohen, B. I.; Vlahcevic, Z. R.; Gregory, D. H.; Halloran, L. G.; Kuramoto, T.; Mosbach, E. H.; Swell, L. (Veterans Admin. Hosp., Richmond, VA 23249). *J. Biol. Chem.* 251(20):6308-6314; 1976.

The *in vivo* conversion of several 5β-cholestane intermediates to primary bile acids was investigated in three patients with total biliary diversion. 5β-[G-^{3}H]-cholestane-$3\alpha,7\alpha$-diol, 5β-[G-^{3}H]-cholestane-$3\alpha,7\alpha,26$-triol, and 5β-[24-^{14}C]cholestane-$3\alpha,7\alpha,25$-triol were administered i.v. (6.39×10^{6} disintegrations/min [dpm], 1.25×10^{6} dpm, and 6.23×10^{5} dpm, resp.). Bile was then collected quantitatively at frequent intervals for the next 21-28 hr. The administered 5β-[G-^{3}H]cholestane-$3\alpha,7\alpha,26$-triol was efficiently converted to cholic and chenodeoxycholic acids in two patients; 61% and 75%, resp., of the administered label was found in primary bile acids. The proportion of labeled cholic to chenodeoxycholic acid was 1.20:1.02 in the bile of these patients, indicating that the C-26 triol was efficiently converted to cholic acid. The ratio of cholic to chenodeoxycholic acid (mass) in the bile of these patients was 1.23:2.32. The 5β-cholestane-$3\alpha,7\alpha$-diol intermediate was also efficiently converted (71%) to both primary bile acids. The cholic to chenodeoxycholic acid ratios by mass and label were similar (2.97 versus 2.23). By contrast, the 5β-cholestane-$3\alpha,7\alpha,25$-triol was poorly converted to bile acids in three patients. Following the administration of this compound, almost all of the administered radioactivity found in the bile acid fraction was in cholic acid (5% to 19%) and very little (<5%) was found in chenodeoxycholic acid. These findings indicate that ring hydroxylation at position 12 is not materially hindered by the presence of a hydroxyl group on the side chain at C-26 in patients with biliary diversion. The labeled C-26-triol that was efficiently converted to both primary bile acids in a proportion similar to that which was observed for the bile acids synthesized by the liver suggests that this 5β-cholestane derivative may be a major intermediate in the synthesis of both cholic and chenodeoxycholic acids.

3360 LIVER REPLACEMENT FOR ALPHA$_1$-ANTITRYPSIN DEFICIENCY. (Eng.) Putnam, C. W.; Porter, K. A.; Peters, R. L.; Ashcavai, M.; Redeker, A. G.; Starzl, T. E. (Veterans Admin. Hosp., 1055 Clermont St., Denver, CO 80220). *Surgery* 81(3):258-261; 1977.

The case report of a 16-yr-old girl with advanced cirrhosis and severe alpha$_1$-antitrypsin deficiency of the homozygous PiZZ phenotype who was treated by orthotopic liver transplantation is presented. After replacement of the liver with a homograft from a donor with the normal PiMM phenotype, the alpha$_1$-antitrypsin concentration in the recipient's serum rose to normal; it had the PiMM phenotype. Two years and 4 months later, chronic rejection necessitated retransplantation. Insertion of a homograft from a heterozygous PiMZ donor was followed by the identification of that phenotype in the recipient's serum. Neither liver graft developed the alpha$_1$-antitrypsin glycoprotein deposits seen with the deficiency state. These observations confirm that this hepatic-based inborn error of metabolism is metabolically cured by liver replacement.

3361 ALPHA-1 ANTITRYPSIN IN LIVER DISEASE. (Eng.) Dzambas, D.; Aleksic, N.; Klaic, A.; Prazic, B. (Inst. Chest Diseases and Tuberculosis, Novi Sad, Yugoslavia). *Acta Med. Iugosl.* 31(1):43-52; 1977.

The diagnostic value of α_1-antitrypsin was studied in 139 patients with acute hepatitis, chronic persistent hepatitis, chronic active hepatitis, and neoplasma hepatitis by the radial immunodiffusion method on agar. The mean value for α_1-antitrypsin was 276.6 ± 44.1 mg% (range 184.5-360.8 mg%). Low values were found in 26 patients (18.72%), high values in 40 (30.93%), and normal values in 70 (50.35%). In all patients with reduced α_1-antitrypsin levels, PAS-positive inclusions occurred in the cytoplasm of hepatocytes.

3362 EVIDENCE FOR RENAL CONTROL OF URINARY EXCRETION OF BILE ACIDS AND BILE ACID SULPHATES IN THE CHOLESTATIC SYNDROME. (Eng.) Summerfield, J. A.; Cullen, J.; Barnes, S.; Billing B. H. (Royal Free Hosp., Pond St., Hamstead, London NW3 2QG, England). *Clin. Sci. Mol. Med.* 52(1):51-65; 1977.

The quantities of bile acids and bile acid sulphates in the urine, serum, and bile from eight patients with intrahepatic or extrahepatic cholestasis were determined by gas-liquid chromatography and gas-liquid chromatography/mass spectrometry to test the hypothesis that urinary bile acid excretion may be controlled by the kidney. The two primary bile acids, cholic acid, and chenodeoxycholic acid, comprised approximately 94% of the total bile acids in bile, 70% in serum, and 64% in urine. The proportion of primary, secondary, and minor bile acids in bile remained relatively constant, regardless of the degree of cholestasis or the total bile acid composition. However, the primary bile acids in serum and urine tended to increase with the total bile acid concentration, with chenodeoxycholic acid frequently predominating in urine. Furthermore the concentration of minor bile acids in urine tended to rise, while that of the secondary bile acids fell with increasing total bile acid concentration, suggesting some renal synthesis of minor bile acids. Epimerization of minor bile acids may also occur in the kidney, since an epimer of cholic acid was discovered in one patient's urine. Biliary bile appeared to become more dilute with increasing severity of cholestasis, as the total bile acid concentration in the urine was negatively correlated with that in the bile. Finally, sulphation of bile acids was very low in the bile (2.1-4.6%), variable in the serum (9.3-50%), but consistently high in the urine (33-72%), the predominant sulphated compound in urine being chenodeoxycholic acid. Unlike serum, the degree of sulphatio was positively correlated with the total bile acid output in urine, indicating a much higher renal clearance of sulphated than nonsulphated bile acids.

363 SERUM-25-HYDROXY-VITAMIN-D IN UNTREATED PARENCHYMAL AND CHOLESTATIC LIVER DISEASE.
Eng.) Long, R. G.; Sherlock, S.; Wills, M. R.;
kinner, R. K. (Royal Free Hosp., London NW3 2QG,
ngland). *Lancet* 2(7987):650-652; 1976.

o determine if vitamin D metabolism is disturbed in
hronic hepatocellular disease, the serum 25-hydroxy-
itamin-D (25-OHD) concentrations were determined in
06 patients and controls. Low mean 25-OHD values
ere found in patients with untreated parenchymal
nd cholestatic liver disease. In the 9 patients
ith alcoholic hepatitis and in the 25 with alcoholic
irrhosis, the mean values were 9.8 ± 5.3 and 8.6 ±
.9 ng/ml, resp.; these values were significantly
ower than those of the controls ($p<0.001$). In six
atients with noncirrhotic chronic active hepatitis
nd 26 patients with lupoid or cryptogenic cirrhosis,
he values were 10.6 ± 6.9 and 10.8 ± 8.0 ng/ml,
esp. ($p<0.01$). Low values were also seen in acute
ulminant viral hepatitis (1.3 ng/ml), the Budd-
hiari syndrome (2.0 ng/ml), the Dubin-Johnson syn-
rome (8.7 ng/ml), and portal vein thrombosis (2.2
g/ml). The mean concentrations among 11 patients
ith symptomatic primary biliary cirrhosis, 5 with
cute large bile duct obstruction due either to car-
inoma or stones, and 11 with chronic cholestasis
ere 5.1 ± 3.8 ng/ml ($p<0.001$), 5.1 ± 4.8 ng/ml
p<0.001), and 6.4 ± 5.5 ng/ml ($p<0.001$), resp. In
even patients with presymptomatic biliary cirrhosis,
he mean value was not significantly different from
hat of controls. It is concluded that in the pres-
nce of significant parenchymal or cholestatic liver
isease, serum 25-OHD concentrations are usually low.
ow serum 25-OHD values may contribute to the etiology
f osteomalacia in chronic liver disease.

364 KINETICS OF [^{14}C]CHOLIC ACID IN FULMINANT HEPATIC FAILURE: A PROGNOSTIC
EST. (Eng.) Horak, W.; Waldram, R.; Murray-Lyon,
. M.; Schuster, E.; Williams, R. (Allgemeines
rankenhaus, Garnisongasse 13, A-1090 Vienna,
ustria). *Gastroenterology* 71(5):809-813; 1976.

he metabolism and kinetics of i.v. ^{14}C-cholic acid
ere investigated in 14 patients with fulminant
epatic failure, 24-36 hr after the development t
f grade IV encephalopathy. Radioactivity was
easured in plasma samples and in the individual
lasma bile acid fractions after separation by thin
ayer chromatography. Plasma disappearance curves
f the free ^{14}C-cholic acid were calculated by
omputerized iterative nonlinear least squares
itting procedure. The disappearance of total
lasma radioactivity was similar in all patients
nd was greatly prolonged compared with healthy
ubjects. However, the plasma disappearance of
ree ^{14}C-cholic acid was significantly faster in
he eight patients who recovered consciousness than
n the six who did not. Plasma disappearance of
ree ^{14}C-cholic acid correlated significantly with
he proportion of conjugated ^{14}C-cholate in plasma.
ll patients in whom more than 70% of plasma radio-
ctivity was in the conjugated fraction 3 hr after
njection survived and left the hospital, whereas
ll of those in whom less that 55% was conjugated died. Measuring the percentage conjugation of ^{14}C-cholate 3 hr after injection may be a useful test of residual liver function in hepatic failure, as a guide to prognosis and in evaluating new forms of treatment.

3365 GALACTOSE ELIMINATION CAPACITY AS A PROGNOSTIC INDEX IN PATIENTS WITH FULMINANT LIVER FAILURE. (Eng.) Ranek, L.; Andreasen, P. B.; Tygstrup, N. (Rigshospitalet, 9 Blegdamsvej, DK-2100 Copenhagen O, Denmark). *Gut* 17(12):959-964; 1976.

In 25 patients with fulminant hepatic failure, the prognostic value of a quantitative liver function test, the galactose elimination capacity, was assessed and compared with routine liver function tests (i.e., prothrombin, bilirubin, transaminases, and ammonia) and clinical features. The galactose elimination capacity was significantly higher ($p<0.05$) in the 5 patients who survived (17.6 ± 4.5 μmol/min/kg) than in the 20 patients who died (12.2 ± 4.3 μmol/min/kg). None of the other liver function tests was significantly different. The values of the galactose elimination capacity overlapped considerably between survivors and nonsurvivors, but all patients with a galactose elimination capacity below 12.8 μmol galactose/min/kg body weight died. The disease among most patients with a galactose elimination capacity greater than 13 μmol who died ran a subacute course. It is suggested that quantitative liver function tests be included when new treatments of fulminant hepatic failure are investigated.

3366 INTRACELLULAR ELECTROLYTE ABNORMALITIES IN FULMINANT HEPATIC FAILURE. (Eng.) Alam, A. N.; Wilkinson, S. P.; Poston, L.; Moodie, H.; Williams, R. (King's Coll. Hosp., Denmark Hill, London, England). *Gastroenterology* 72(5, Part 1): 914-917; 1977.

The sodium, potassium, and water content of peripheral blood WBC was determined in 30 patients with fulminant hepatic failure to investigate possible electrolyte abnormalities in the intracellular compartment, which might contribute toward hyponatremia in these patients. The mean potassium level was significantly lower in the patients than in 21 controls (2.95 ± 0.53 l/kg dry weight and 2.67 ± 0.07 l/kg, resp., $p<0.02$), but the sodium and water concentrations were significantly increased (123 ± 53 mmol/kg versus 80 ± 5 mmol/kg, $p<0.001$). With recovery of liver function, the WBC sodium content fell initially to below normal, with values subsequently returning to the normal range some weeks later. The WBC sodium content was inversely correlated to the plasma sodium concentration ($p<0.001$), suggesting that a shift of sodium into the intracellular compartment might contribute to the hyponatremia found in many patients with fulminant hepatic failure.

3367 H_2-RECEPTOR ANTAGONISTS AND ANTACIDS IN THE PREVENTION OF ACUTE GASTROINTESTINAL HAEMORRHAGE IN FULMINANT HEPATIC FAILURE: TWO CONTROLLED TRIALS. (Eng.) Macdougall, B. R. D.;

Bailey, R. J.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5, England). *Lancet* 1(8012):617-619; 1977.

The value of antacids and of cimetidine and metiamide in the prevention of gastrointestinal bleeding was studied in 75 patients with fulminant hepatic failure and grade IV coma. The first 25 patients were randomly allocated to treatment with or without antacid; 13 received 20 ml magnesium hydroxide every 4 hr via nasogastric tube. Twenty-six of the remaining 50 patients received metiamide (150 mg) or cimetidine (100 mg/hr) i.v. In the antacid trial, 3 of the 13 treated patients bled, while 6 of the 12 untreated patients bled; this was not a statistically significant difference. Only 1 of the 26 patients treated with a histamine H_2-receptor antagonist bled, compared with 13 of the 24 controls ($p<0.001$). Blood transfusion requirements in patients treated with H_2-receptor antagonists were significantly less than in controls (an average of 0.5 and 2.6 l, resp.). This also applied to patients treated with antacids (average 0.8 l). Two control patients who recovered from grade IV coma subsequently died from severe gastrointestinal bleeding from erosions; this was not seen in any patient treated with H_2-receptor antagonists, and all patients who recovered from grade IV coma in that group left the hospital. H_2-receptor antagonists are effective in the prevention of acute gastrointestinal hemorrhage in patients with fulminant hepatic failure.

3368 SERUM BILE ACID PATTERNS IN NEONATAL HEPATITIS AND EXTRAHEPATIC BILIARY ATRESIA.

(Eng.) Javitt, N. B.; Keating, J. P.; Grand, R. J.; Harris, R. C. (New York Hosp.-Cornell Medical Center, 525 E, 68th St., New York, NY 10021). *J. Pediatr.* 90(5):736-739; 1977.

Serum bile acid patterns were determined in 31 jaundiced infants to evaluate their usefulness in the diagnosis and management of neonatal liver disease. The infants ranged in age from 4 days to 24 weeks. Fifteen infants with extrahepatic biliary atresia had a mean concentration of serum bile acids of 90 ± 47 μg/ml; 16 infants with neonatal hepatitis had a mean concentration of 60 ± 35.5 μg/ml. The chenodeoxycholate/cholate ratio was greater than one in 13 infants (87%) with atresia and in 10 infants (66%) with neonatal hepatitis. Except for the tendency of a higher total concentration of serum bile acids in infants with atresia, a single serum bile acid value does not differentiate neonatal hepatitis from extrahepatic biliary atresia. The high proportion of chenodeoxycholate in extrahepatic atresia is different from the pattern in other types of cholestatic disease and may reflect an underlying hepatitis.

3369 ANTI-HBc TITER IN RELATION TO THE ETIOLOGICAL ROLE OF HEPATITIS B VIRUS IN PRIMARY HEPATOCELLULAR CARCINOMA.

(Eng.) Furuta, S.; Nagata, A.; Kiyosawa, K.; Akahane, Y.; Koike, Y.; Sahara, T.; Oda, M.; Mayumi, M.; Tsuda, F. (Faculty Medicine, Shinshu Univ., 3-1-1 Matsumoto, Nagano-Prefecture, Japan). *Acta Hepatogastroenterol.* 24(1):3-6; 1977.

To study the etiological role of hepatitis B virus (HBV) in relation to primary hepatocellular carcinoma (PHC), the antibody to hepatitis B core antigen (anti-HBc) in the sera of 31 PHC patients was surveyed by the immune adherence hemagglutination method. Twenty-two patients were anti-HBc-positive (71.0%), and 51.6% were hepatitis B surface antigen (HBsAg)-positive. A high anti-HBc titer ($>2^{10}$) was observed in 15 of the 22 patients who were anti-HBc-positive, reflecting possible current HBV infection. The remaining seven patients had a titer lower than 2^8; five of these patients had neither HBsAg nor anti-HBs in their sera. Among 37 anti-HBs-positive blood donors with no confirmed liver disease, 34 were anti-HBc-positive; the serum titer was less than 2^9, which may reflect previous HBV infection. The results indicate that the determination of the prevalence and the titer of anti-HBc is useful in studying the relation between HBV and PHC.

3370 A CAUSE OF HYPERAMYLASEMIA ASSOCIATED WITH CHRONIC LIVER DISEASE.

(Eng.) MacGregor, I. L.; Zakim, D. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Gastroenterology* 72(3):519-523; 1977.

In an attempt to identify the tissue of origin of hyperamylasemia in three patients with chronic active hepatitis, their serum was isoelectrically focused. The isoamylase patterns were compared to those of pancreatic and salivary amylase. The apparent salivary gland origin of the excessive blood amylase in the patients was substantiated by radiological demonstration of parotid sialoectasia in one patient and histological evidence of sialoadenitis in another. Further evidence was the coincident isoelectric points of the predominant isoamylase in the sera of the liver disease patients and of patients with parotid inflammatory disease. Hyperamylasemia associated with chronic liver disease may be of salivary gland origin and, as such, forms part of the spectrum of extrahepatic manifestations of chronic active hepatitis.

3371 LIVER-CELL-MEMBRANE AUTOANTIBODY SPECIFIC FOR INFLAMMATORY LIVER DISEASES.

(Eng.) Tage-Jensen, U.; Arnold, W.; Dietrichson, O.; Hardt, F.; Hopf, U.; Meyer Zum Buschenfelde, K. H.; Nielsen, J. O. (Kommunehospitalet, Copenhagen, Denmark). *Br. Med. J.* 1(6055):206-208; 1977.

Sera from 361 patients with various liver diseases and 274 patients with primary nonhepatic diseases, many associated with non-organ-specific autoantibodies, were examined to elucidate the disease specif city of an autoantibody directed against liver cell membrane (LMA). LMA was detected by an immunofluores cence technique using rabbit hepatocytes in 27 of 72 patients with hepatitis B surface antigen (HBsAg)-neg ative chronic active hepatitis and in 17 out of 28 patients with HBsAg-negative nonalcoholic cirrhosis. Only two patients had LMA and HBsAg, and both had chronic active hepatitis. One patient with extrahepa tic disease had LMA, and this patient had biochemical evidence of liver disease. There is a close correlation between the presence of LMA and HBsAg-negative chronic inflammatory liver disease, and its detection may help in diagnosis.

3372 SERUM α-FETOPROTEIN IN PATIENTS WITH MASSIVE HEPATIC NECROSIS.

(Eng.) Bloomer, J. R.; Waldmann, T. A.; McIntire, K. R.; Klatskin, G. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *Gastroenterology* 72(3):479-482; 1977.

The serum α-fetoprotein (AFP) level was measured in 12 patients with massive hepatic necrosis to determine the time of onset of increased serum AFP relative to the duration of the illness, as this may provide information about the course of regeneration. The etiology of hepatic necrosis was viral hepatitis in 10 patients, halothane hepatitis in 1 patient, and ischemic necrosis in 1 patient. Of the 12 patients, 2 died on or before the ninth day of illness; their serum AFP levels were normal at all times (14-24 ng/ml). Increased serum AFP levels (>40 ng/ml) were not observed in any patient before the ninth day of illness. AFP levels were significantly elevated after the 9th day in eight of the nine patients who died between the 10th and 60th day of illness and in the one patient who survived. All nine patients with increased serum AFP levels exhibited histological evidence of hepatic regeneration; the remaining parenchyma showed variable degrees of pleomorphism, and the hepatocytes were arranged in thick plates, often forming rosettes and pseudoducts, some of which contained bile. These findings indicate that the rise in serum AFP in massive hepatic necrosis is related to the duration of survival after the onset of illness, but does not necessarily imply ultimate recovery. Because available evidence suggests that the serum AFP level reflects hepatic regenerative activity, it appears that the onset of regeneration in fulminant hepatitis is delayed until the second week of illness.

3373 DEFICIENT ACTIVITY OF HEPATIC PYRUVATE DEHYDROGENASE AND PYRUVATE CARBOXYLASE IN REYE'S SYNDROME.

(Eng.) Robinson, B. H.; Gall, D. G.; Cutz, E. (Hosp. Sick Children, 555 University Ave.. Toronto, Ontario, M5G 1X8, Canada). *Pediatr. Res.* 11(4):279-281; 1977.

To determine whether the hypoglycemia and lactic acidemia frequently observed in Reye's syndrome are due to decreased mitochondrial pyruvate carboxylase and pyruvate dehydrogenase, resp., the activities of these enzymes were measured in postmortem samples from six patients with Reye's syndrome and from seven controls. The activities of the two exclusively extramitochondrial enzymes, glucose-6-phosphatase and fructose-1,6-diphosphatase, were within the normal range. The activities of pyruvate carboxylase and pyruvate dehydrogenase were below the control levels in every case, the average being 21.7% of the lowest control value for pyruvate carboxylase and 11.6% of that for pyruvate dehydrogenase. Impaired pyruvate metabolism appears to be another feature in Reye's syndrome. This supports the hypothesis that nonselective deletion of mitochondrial enzymes due to disruption of mitochondrial integrity is a factor in the pathogenesis of Reye's syndrome.

3374 VITAMIN B_6 DEFICIENCY IN CHRONIC LIVER DISEASE--EVIDENCE FOR INCREASED DEGRADATION OF PYRIDOXAL-5'-PHOSPHATE.

(Eng.) Labadarios, D.; Rossouw, J. E.; McConnell, J. B.; Davis, M.; Williams, R. (King's Coll. Hosp., London, SE5 England). *Gut* 18(1):23-27; 1977.

Plasma levels of pyridoxal-5'-phosphate (PLP) and the levels of its main metabolite, 4-pyridoxic acid, were used as an index of vitamin B_6 nutrition in 31 alcoholic and nonalcoholic patients with decompensated cirrhosis or hepatitis. Plasma PLP levels were significantly lower than normal in 22 patients, the mean values for the liver disease and control patients being 3.0 and 11.7 ng/ml, resp. There was no significant difference in plasma PLP levels between those with liver disease due to alcohol and those with other liver diseases. When i.v. supplements with pyridoxine hydrochloride were given to nine patients (50 mg, b.i.d.) for 1 week, only 33% responded with an increase in plasma PLP. In contrast, all 11 patients given PLP (50 mg b.i.d., 1 week) responded, although peak plasma levels were variable, the response being significantly less than that found in normal control subjects. After supplementation with pyridoxine hydrochloride, and with PLP, the urinary excretion of 4-pyridoxic acid was higher in patients who showed the least increase in plasma PLP levels. Although impaired phosphorylation of pyridoxine hydrochloride may be one factor, the most likely explanation for these findings is an increased rate of PLP degradation, which may be important in the pathogenesis of vitamin B_6 deficiency in patients with severe liver disease.

3375 REDUCED OXIDASE ACTIVITY IN THE CAERULOPLASMIN OF TWO FAMILIES WITH WILSON'S DISEASE.

(Eng.) Gollan, J. L.; Stocks, J.; Dormandy, T. L.; Sherlock, S. (1120 HSW Dept. Medicine, Univ. California, San Francisco, CA 94143). *J. Clin. Pathol.* 30(1):81-83; 1977.

Ceruloplasmin was determined immunologically and by copper oxidase activity in 25 normal subjects, 20 patients with Wilson's disease, and 80 patients with chronic liver disease. Repeated estimation in four patients with Wilson's disease and two heterozygous mothers from two families revealed a consistent reduction in the copper oxidase activity of ceruloplasmin (12-32 U copper oxidase activity/mg ceruloplasmin) relative to the values obtained in normal subjects, patients with chronic liver disease, and other Wilson's disease patients (mean 65-79 U/mg). The functional abnormality in ceruloplasmin observed in these two families may be an inherited variant, which does not appear to be due to the presence of a serum inhibitor of copper oxidase.

3376 BREATH ANALYSIS OF MICROSOMAL FUNCTION IN HEPATIC AND EXTRAHEPATIC DISEASE [Abstract].

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

3405 THE NATURE OF THE DOSE-RESPONSE RELATIONSHIP OF PHOTOTHERAPY FOR NEONATAL HYPERBILIRUBINEMIA. (Eng.) Tan, K. L. (Univ. Singapore, Republic of Singapore). *J. Pediatr.* 90(3):448-452; 1977.

The dose-response relation of phototherapy for neonatal hyperbilirubinemia was analyzed in 110 Chinese infants having bilirubin levels of 15 mg/dl and above. The infants were subdivided into ten groups. Each group was subjected to phototherapy of different intensity with use of Philips day light (TL 20 W/54) and special blue (TLAK 40 W/03) fluorescent lamps. The 24-hr decline in bilirubin level was used to evaluate the efficacy of phototherapy. The rate of response progressively decreased with increasing radiance until a "saturation point" (585 $\mu W/cm^2$ in 425-472 nm range and 770 $\mu W/cm^2$ in 400-800 nm range) was reached, beyond which further increases in radiance serve no purpose. There was a 37% reduction in bilirubin level at the saturation point. Blue lamps (24 hr decline, 4.3-6.7 mg/dl) were more efficient than white lamps (24 hr decline, 1.6-4.7 mg/dl). The minimal regression at which phototherapy is effective was 15.25 $\mu W/cm^2$ in the 425-475 nm range and 16.29 $\mu W/cm^2$ in the 400-480 nm range. Time required for bilirubin levels to decrease to less than 11 mg/dl was shortened (2 days) in groups receiving increased radiance. Pyrexia, the main disadvantage of intense phototherapy, was controlled effectively by increasing ventilation. No infant had to undergo phototherapy a second time for recurrent hyperbilirubinemia.

3406 TEMPORARY INTESTINAL LACTASE DEFICIENCY IN LIGHT-TREATED JAUNDICED INFANTS. (Eng.)

Bakken, A. F. (Rikshospitalet, Univ. Oslo, Oslo 1, Norway). *Acta Paediatr. Scand.* 66(1):91-96; 1977.

To determine whether the diarrhea seen in six newborn, jaundiced infants treated with light was due to a temporary inhibition of the intestinal brush-border lactase by increased amounts of unconjugated intestinal bilirubin, their intestinal lactase activity was measured by the lactose tolerance test and compared to that in eight normal controls. The ability to hydrolyze lactose was minimal in the jaundiced infants during light-treatment, compared to the controls in whom lactose was well absorbed. The histochemical investigation of p.o. intestinal biopsy specimens revealed no intestinal lactase activity in the jaundiced infants. When the jaundiced infants were given lactose-free diets, the stools normalized. The effect was reversed when breast milk was given while the infants were still jaundiced and light-treated. These findings indicate that the increased amounts of unconjugated bilirubin in the intestine of jaundiced infants during light-treatment inhibit the intestinal brush border lactase. When the icterus fades, the lactase is again active. Thus, light-treated infants with diarrhea should be given a lactose-free diet; when the baby is no longer icteric, breast milk or other lactose-containing diet can be reintroduced.

3407 CONJUGATED HYPERBILIRUBINEMIA IN INFANCY ASSOCIATED WITH PARENTERAL ALIMENTATION.

(Eng.) Bernstein, J.; Chang, C. H.; Brough, A. J.; Heidelberger, K. P. (William Beaumont Hosp., Royal Oak, MI 48072). *J. Pediatr.* 90(3):361-367; 1977.

Histopathologic and electron microscopic studies of liver biopsy, done to exclude anatomic obstruction of the biliary tract in five prematurely born infants (32 to 34 weeks) showing respiratory distress syndrome, are presented. These infants developed conjugated hyperbilirubinemia during i.v. alimentation with Cutter casein protein hydrolysate (2.5 g/kg/day). Each had undergone a segmental intestinal resection for necrotizing enterocolitis. The biopsies in all five infants showed cholestasis and hepatocellular damage. Four of these infants had hyperbilirubinemia, with serum concentrations greater than 2.0 mg/dl (4-7 weeks). One infant developed a concentration of bilirubin of 1.7 mg/dl on the 63rd day of life. Maximal concentrations of bilirubin (4.1-12.6 mg/dl) occurred from 7 to 15 weeks after surgery. There appeared to be little correlation between the degree of bile stasis and hyperbilirubinemia. Cholestasis was most severe in the central portions of the lobules, where distended canaliculi contained plugs of greenish-brown material. The hepatocytes were swollen, with vesiculation of the peripheral cytoplasm, and contained large amounts of granular bile and lipofuscin pigment. Liver cells from two biopsy specimens contained small tangles of smooth membranes, corresponding to the abnormality "microsomal lipid peroxidation." Present findings implicate the protein hydrolysate in the hepatic abnormality, because jaundice always subsided following permanent discontinuation of i.v. alimentation.

3408 DIAGNOSTIC SIGNIFICANCE OF ALPHA-FETOPROTEINS IN NEONATAL HYPERBILIRUBINAEMIAS AND PRIMARY CANCER OF THE LIVER IN ADULTS. (Eng.)

Milosavljevic, J.; Stajic, M.; Vilhar, N. (General Hosp. Zemun, Vukova 9, 11080 Zemun, Yugoslavia). *Acta Hepatogastroenterol.* 24(1):30-33; 1977.

The frequency of serum α-1-fetoprotein (AFP) was determined by immunoprecipitation electrophoresis in 16 patients with primary hepatocellular carcinoma and in 50 neonates with hyperbilirubinemia. Among 94 healthy control infants under 14 days of age, AFP was detected in all but two; AFP did not occur in the sera of 20 control infants aged 20-30 days, nor was it present in adult controls. AFP was present in 15 of 16 jaundiced neonates under 7 days of age and was present in all 13 7- to 14-day-old jaundiced infants. Among seven 15- to 21-day-old jaundiced infants, six sera were AFP-positive. Only one of five 22- to 30-day-old infants were AFP-positive, but AFP was present in nine 1- to 3-month old infants with bile duct malformations. Among the 16 patients with liver cancer, 43.7% had AFP-positive sera, while none of 40 adults with other cancers had AFP. AFP in adult subjects indicates primary hepatocellular carcinoma in the liver; however, the absence of AFP does not necessarily rule out this diagnosis.

3409 DIFFERENTIAL DIAGNOSIS OF PERSISTENT CHOLESTATIC JAUNDICE IN INFANCY. (Eng.)

Poley, J. R. (Zentrum fur Innere Medizin und Kinderheilkunde, Universitats-Kinderklinik, Prittwitzstrasse 43, 79 Ulm, Donau, W. Germany). *South. Med. J.* 70(1):91-94; 1977.

The differential diagnosis of persistent cholestatic jaundice in infancy is reviewed, with particular emphasis on the diagnosis of biliary atresia. Most infants with persistent cholestatic jaundice have either a form of neonatal hepatitis, biliary hypoplasia, or biliary atresia. Intrahepatic cholestasis is caused by neonatal hepatitis (more appropriately designated neonatal hepatic inflammatory disease), α_1-antitrypsin deficiency, Byler's disease, and familial recurrent cholestasis, with or without lymphedema. The most common cause of obstruction of the extrahepatic biliary tree is the fibrous obliteration and scarring of portions of the hepatic ducts and/or the common duct. The extrahepatic ductal system may even be completely absent, while the true atresia of the common duct or the hepatic ducts is less common. Cholestyramine-based tests and the determination of 5'-nucleotidase levels are the most useful tests for the diagnosis of biliary atresia. The latter is useful in distinguishing between intrahepatic and extrahepatic cholestasis. In one study, 5'-nucleotidase levels were consistently higher in biliary atresia (9 patients) than in neonatal hepatitis (27 patients). The cholestyramine-based tests include cholestyramine combined with either the iodinated rose bengal xcretion test or the quantitative determination f lipoprotein X (LP-X). The latter test is the ost useful. The absence of LP-X in the serum of a aundiced infant beyond 4 weeks of age rules out the iagnosis of biliary atresia.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

413 NEONATAL HEPATITIS AND ALPHA-1-ANTITRYPSIN DEFICIENCY: THE PROGNOSIS IN FIVE
ATIENTS. (Eng.) Hirschberger, M.; Stickler, G. B. Mayo Graduate Sch. Medicine, Rochester, MN). *Mayo lin. Proc.* 52(4):241-245; 1977.

ive patients who presented with the neonatal hepaitis syndrome associated with α-1-antitrypsin (α-1-AT) eficiency (PiZ) were followed for up to 21 yr. o patients developed cirrhosis at ages 5 and 8 yr, esp. The duration of neonatal cholestasis in these atients was 3 and 2 months, resp., and their α1AT evels at the time of cholestasis were 78 and 45 g/dl, resp. The 8-yr-old patient has ascites and levated SGOT; the other patient is clinically well, ut the SGOT and alkaline phosphatase levels are levated, and psychomotor development is delayed. he three remaining patients, aged 1, 9, and 21 yr, re asymptomatic. The first two patients have nor- l liver function tests, and the latter patient s a mild elevation of SGOT (51 U/l). She is linically well, except for a seizure disorder. The iver biopsy revealed mild portal fibrosis with reserved lobular architecture. The prognosis for atients with α-1-AT deficiency (PiZ) presenting with eonatal hepatitis is not necessarily grave, a findng that differs from previous observations.

14 STUDY OF AN EPIDEMIC OF JAUNDICE, PRESUMABLY DUE TO TOXIC HEPATITIS, IN NORTHWEST
NDIA. (Eng.) Tandon, B. N.; Krishnamurthy, L.; oshy, A.; Tandon, H. D.; Ramalingaswami, V.; handari, J. R.; *et al.* (All-India Inst. Medical ciences, Ansari Nagar, New Delhi-110016, India). *astroenterology* 72(3):488-494; 1977.

Detailed clinical features, appropriate laboratory tests, and liver biopsies were studied in 200 patients in whom an epidemic of jaundice, probably due to toxic hepatitis, occurred. The epidemic affected dogs first, then the humans in three adjoining districts in India. A retrospective epidemiological survey was carried out. The disease had a subacute onset, starting with high fever followed by rapidly progressive jaundice. Ascites appeared simultaneously and soon became quite massive. Hepatomegaly was recorded when ascites decreased. Liver function tests suggested cholestatic jaundice. The mortality rate in the hospital was 10%. Clinical features in dogs were similar, but mortality was almost 100%. Liver histology was characterized by edema and collagenization of the central veins, never with thrombosis; cholangiolar proliferation; moderate to severe ballooning of the hepatocytes; perisinusoidal fibrosis; cholestasis; and finally, cirrhosis with reverse lobulation. The etiology of this hepatitis epidemic could not be unequivocally established; critical analysis of the data suggests that some food toxin may have been a factor in the outbreak.

3415 REVERSIBLE OXACILLIN HEPATOTOXICITY. (Eng.) Olans, R. N.; Weiner, L. B. (Upstate Medical Center, 750 East Adams St., Syracuse, NY 13210). *J. Pediatr.* 89(5):835-838; 1976.

The cases of eight patients with reversible hepatotoxicity secondary to the administration of oxacillin are presented. The patients included seven children, ranging in age from 10.5 months to 10.5 yr, and a 31-yr-old man. The patients received oxacillin (150-400 mg/kg/day, i.v.) for 9-35 days in the treatment of staphylococcal infections. All patients developed elevated SGOT and SGPT levels (maximal values 136-1,110 IU and 31-1,359 IU, resp.), but all remained asymptomatic and anicteric. Peripheral eosinophilia was present in five patients. Two to six days after nafcillin or penicillin G was substituted for oxacillin, the liver enzyme levels began to drop, and they returned to normal in 3-180 days. Change of medication to an alternative penicillinase-resistant penicillin or to penicillin G is suggested as a safe procedure for completion of antistaphylococcal therapy in patients who develop oxacillin-related hepatotoxicity.

3416 FREQUENCY OF RENAL IMPAIRMENT IN PARACETAMOL OVERDOSE COMPARED WITH OTHER CAUSES OF ACUTE LIVER DAMAGE.

(Eng.) Wilkinson, S. P.; Moodie, H.; Arroyo, V. A.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5, England). *J. Clin. Pathol.* 30(2):141-143; 1977.

To determine whether paracetamol overdose has a specific nephrotoxic action, the frequency of renal failure was analyzed in 160 patients with fulminant hepatic failure and grade IV encephalopathy, separated according to etiology. In addition, the frequency of renal failure in 90 cases of paracetamol overdose with less severe hepatic damage was compared with that found in 100 cases of acute viral hepatitis with comparable abnormalities in liver function tests, and assays for endotoxin were carried out in 14 patients with paracetamol overdose. Although the frequency of renal failure appeared to be higher in the 53 patients with paracetamol overdose (53%) than in the 68 patients with acute viral hepatitis (38%) or in hepatic failure attributable to other causes (38%), none of the differences achieved statistical significance. Similar results were achieved in the 90 patients with less severe hepatic damage. Thirteen of 14 patients with fulminant hepatic failure from paracetamol overdose who had developed renal failure had a positive *Limulus* lysate assay for systemic endotoxemia, compared with only 1 of the 7 tested who did not have renal failure ($p<0.001$). In 21 patients with fulminant hepatic failure due to other causes in whom the *Limulus* assay was performed, the assay was positive in all 12 with renal failure, but negative in the other 9 ($p<0.001$). Similarly in eight patients with less severe liver damage due to paracetamol, a positive assay was obtained in only the two patients with renal failure ($p=0.05$). The findings do not support the concept that paracetamol, taken in overdose, has a specific nephrotoxic action, but do support the hypothesis that renal failure in fulminant hepatic failure is related to endotoxemia.

3417 OCCUPATIONAL PATHOLOGY OF THE LIVER PROVOKED BY TOLUYLENE-DIISOCYANATE.

(Rus.) Sharonova, Z. V.; Kryshanovskaya, N. A. (Inst. Indus trial Hygiene and Occupational Diseases, Gor'kii, USSR). *Gig. Tr. Prof. Zabol.* (11):27-31; 1976.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

3418 HEPATITIS B INFECTIONS IN EXPATRIATE DOCTORS IN PAPUA NEW GUINEA.

(Eng.) Woodfield, D. G. (Auckland Blood Transfusion Service, P.O. Box 5546, Wellesley St., Auckland C1, New Zealand). *Med. J. Aust.* 2(16):595-596, 598-599; 1976.

The clinical and serological effects of transferring to an area of high hepatitis B surface antigen (HBsAg) prevalence were studied by determining the frequency of hepatitis B infection in European doctors and in nonmedical expatriates working in Papua New Guinea. The average length of residence in New Guinea for doctors was 5.09 yr (range 0.08-30.0 yr). Clinical hepatitis was reported in 42 of 189 doctors, and 29 of these doctors reported hepatitis while in New Guinea. The total person-years of residence in New Guinea was 962, representing an overall risk for all age groups of 3.01%. Among 115 blood samples received from the doctors, evidence o exposure to hepatitis B virus was found in 48 (41.7%). Of the 22 doctors with hepatitis, 15 (68.2%) had HBsAg or antibody to HBsAg (anti-HBs), a significantly higher proportion than doctors with out clinical hepatitis (35.3%, $p<0.001$). Among the 636 nonmedical expatriates who had lived in New Guinea for a mean of 5.94 yr (range 0.08-36.0 yr), the frequency of hepatitis was 10.7%, with 5.0% of the hepatitis occurring in New Guinea. The over all risk for hepatitis was 1.8%, a figure similar to that reported for American missionaries abroad.

3419 CONTAGIOUSNESS OF ACUTE HEPATITIS B: SEC ONDARY ATTACK RATES IN HOUSEHOLD CONTACTS

(Eng.) Koff, R. S.; Slavin, M. M.; Connelly, L. J. D.; Rosen, D. R. (Veterans Admin. Hosp., 150 South luntingdon Ave., Boston, MA 02130). *Gastroenterology* 72(2)297-300; 1977.

o define the hazard of household exposure to patients ith acute hepatitis B, in the absence of persistent epatitis B surface antigen (HBsAg), 98 household ontacts of 42 patients with the acute disease were nterviewed and tested for HBsAg, antibody to HBsAg anti-HBs), and serum transaminases shortly after dentification and at 3-month intervals for at least 2 months. Most of the index cases with acute hepaitis B were young men, and many had used illicit rugs parenterally before the onset of illness. At he initial testing, HBsAg was detected in three ousehold contacts, and two of these were carriers ith elevated serum transaminase levels. The third BsAg-positive contact developed acute hepatitis ithin 2 weeks. This appeared to represent a corimary infection. Fourteen contacts had anti-HBs n initial evaluation and were considered to be mmune as a result of prior experience with hepaitis B. Of 81 susceptible contacts (neither BsAg nor anti-HBs on initial screening), 13 were pouses or sexual partners, and 2 of these developed cute hepatitis B at 4 and 6 months after the onset f illness in their respective index cases; another eveloped anti-HBs at 6 months. Thus, 3 (23%) of 13 xposed spouses or sexual partners developed evience of hepatitis B infection during the surveilance period. In contrast, no evidence of hepatitis infection related to household exposure was found n 68 parents, siblings, and other domestic contacts. hese data confirm the contagiousness of hepatitis for household contacts of acute cases and suggest hat the risk is confined to spouses and sexual artners. These persons appear to be prime candiates for prophylaxis with hepatitis B immune globlin.

420 NOSOCOMIAL VIRAL HEPATITIS B: A CLUSTER AMONG STAFF WITH SUBSEQUENT TRANSMISSION 0 PATIENTS. (Eng.) Snydman, D. R.; Hindman, S. H.; ineland, M. D.; Bryan, J. A.; Maynard, J. E. Center Disease Control, Atlanta, GA 30333). *Ann. ntern. Med.* 85(5):573-577; 1976.

n outbreak of nosocomial hepatitis B among hospital taff and patients is described. In a 2-month perod, four cases of hepatitis B occurred in hospital taff. Three months later, two patients, hospitalzed for open-heart surgery when the staff members ad been infected, developed acute hepatitis B. era from all six ill individuals were subtype *ayw* and -determinant positive. Epidemiologic investigation howed that the four staff members had been exposed months earlier to an asymptomatic hepatitis B urface antigen (HBsAg)-positive patient who was also positive. To determine transmission from staff to atients, a study of 17 open-heart surgery patients as undertaken. Four of 17 were either HBsAg- or anti-Bs (antibody to HBsAg)-positive. No correlation beween infection and contact with three of four ill taff members or receipt of blood products was noted. owever, 22 (46%) of 48 arterial blood gas specimens ad been obtained from infected patients by one staff ember; this compared with seven (4%) of 157 specimens she obtained from control subjects ($p<0.001$). Furthermore, she handled indwelling arterial cannulae 25 (76%) of 33 times in infected patients, compared with 3 (3%) of 95 times in control subjects ($p<0.001$). Transmission may have occurred via the arterial cannulae from a severe exudative dermatitis on the therapist's hands.

3421 REACTIVATION OF HEPATITIS B AFTER TRANSPLANTATION OPERATIONS. (Eng.) Nagington, J.; Cossart, Y. E.; Cohen, B. J. (Public Health Lab., Hills Rd., Cambridge CB2 2QW, England). *Lancet* 1(8011):558-560; 1977.

A transplant and dialysis unit has been monitored for hepatitis-B virus (HBV) infection since 1968. The onset of antigenemia occurred in six patients. When the first serum of each patient admitted was examined for the antibody to hepatitis B core antigen (anti-HBc), 23 of 380 patients were positive. Since the presence of anti-HBc is taken to be evidence of previous infection, the occurrence of antigenemia in three of the positives when they were immunosuppressed after transplantation is believed to be due to reactivation of latent infection. This is a new factor to be considered in the control of hepatitis B after transplantation.

3422 VIRAL HEPATITIS IN INFANTS DURING THE FIRST SIX MONTHS OF LIFE (CLINICO-LABORATORY CHARACTERISTICS). (Rus.) Bulatkina, F. G. (Dept. Infectious Diseases in Children, Leningrad Pediatric Medical Inst., Leningrad, USSR). *Pediatriia* (7):24-26; 1976.

A group of 309 children (<6-months-old) with viral hepatitis (VH) was surveyed. During pregnancy, 33.3% of patients' mothers had toxicosis and hypertension; 38.4% had premature birth; 31.3% of children had a history of pneumonia; and 9.1% had sepsis. Severe forms of VH were observed in 48.2% of the children (lethality 11.3%). Severe VH was recorded in 54.1% of 3-month-old children, compared to 36.1% of 6-month-old children. The disease was acute in 89.4% of the patients, protracted in 8.7%, and chronic in 1.9%. Duration of the preicteric period comprised only 3.8 to 5.65 days. First symptoms were enlargement of the liver (85.4%), loss of appetite (34.2%), and vomiting (26.6%). Duration of the icteric period ranged from 21.3 to 69.2 days. Children with icteric hepatitis had elevated bilirubin levels (11.8 ± 0.5 mg%, compared to 2.8 ± 0.2 mg% in controls) and significantly decreased prothrombin levels (53.6 ± 2.8% in patients with severe VH, and 14.0 ± 3.3% in patients in coma). The most characteristic features of VH in these infants were the severity and irregularity of the course.

3423 TREATMENT OF ACUTE LIVER DYSTROPHY IN VIRAL HEPATITIS DURING PREGNANCY. (Rus.) Farber, N. A.; Ketiladze, E. S.; Gubsky, L. V.; Malyshev, N. A. (D. I. Ivanovsky Inst. Virology, Acad. Medical Sciences USSR, Moscow, USSR). *Ter. Arkh.* 48(12):40-45; 1976.

During 1956-1975, 1,357 pregnant women underwent treatment for viral hepatitis (14 patients died of acute hepatic insufficiency). The incidence of serum hepatitis and infectious hepatitis among the pregnant women was 73.6% and 7.2%, resp., compared to 46.2% and 37.8%, resp., among nonpregnant patients. The frequency of hepatitis B antigen was found to be significantly greater among the pregnant women (45.7%) than among the nonpregnant women (34.3%). The case histories of three patients with serum hepatitis and jaundice are presented (hepatitis B antigen was detected in 2 patients). Two patients had 30-week and 39-week pregnancy, resp., and the third patient was admitted after premature delivery. They developed acute hepatic insufficiency with encephalopathy (drowsiness, disorientation, mental confusion); all patients showed marked diminution of the liver, progressively worsened jaundice, and decreasing prothrombin and sublimate test indices. All three patients had negative diuresis, with pronounced retention of fluid, and edema. Treatment included diuretics, attempts to control cerebral edema, and immunotherapy with gammaglobulin and hepatitis B antibody-containing plasma. All patients were discharged from the hospital in good health.

3424 VIRAL HEPATITIS AND THE PROBLEM OF CHOLESTASIS IN PREGNANT WOMEN.

(Rus.) Rychnev, V. E. (Dept. Infectious Diseases, Rostov Medical Inst., Rostov-on-Don, USSR). *Vrach. Delo* (10):134-139; 1976.

Of 334 pregnant women with jaundice of different etiologies, 84 had jaundice due to the intrahepatic cholestasis (cholestatic hepatosis, CH). First symptoms of CH were pruritus, pain in the right hypochondrium and epigastrum, loss of appetite, and vomiting; 51% of the patients had enlargement of the liver, and 11% had enlargement of the spleen. Of 84 patients with CH, 14 had premature birth, and 11 had metrorrhagia immediately after delivery. Perinatal child lethality was 20 ± 6%. Of 51 women with CH who were followed up for 5 yr, 4 developed chronic hepatitis, and 25 had lesions of biliary ducts and gallbladder; only 20 women were disease-free.

3425 CLINICAL SIGNIFICANCE OF SEPARATE QUANTITATIVE ASSESSMENT OF BILIRUBIN MONOGLUCURONIDE AND BILIRUBIN DIGLUCURONIDE IN THE BLOOD SERUM OF PATIENTS WITH JAUNDICE OF DIFFERENT ETIOLOGY.

(Rus.) Sorinson, S. N.; Vanesyan, A. S. (S. M. Kirov Medical Inst., Dept. Infectious Diseases, Gor'kiy, USSR). *Ter. Arkh.* 49(2):67-69; 1977.

Fractional analysis of hyperbilirubinemia was performed in 245 patients with jaundice of different etiologies. There were 155 patients with viral hepatitis, 21 with functional hyperbilirubinemia, 17 with hemolytic disease, 31 with chronic hepatitis and cirrhosis, and 21 with neoplasms. The combined Nosslin diazotest and extractive Weber-Schalm test were used for quantitative assessment of bilirubin monoglucuronide (BMG) and bilirubin diglucuronide (BDG) fractions in blood serum. Patients with viral hepatitis showed a gradual and progressive increase in the BMG content from 1.15 ± 0.03 mg% in patients with mild disease to 7.03 ± 1.3 mg% in patients with severe disease. The BMG level was 0.31 ± 0.06 mg% in patients with hemolytic disease 0.9 ± 1.17 mg% in patients with chronic hepatitis, 3.3 ± 0.9 mg% in patients with cirrhosis, 4.7^{7} ± 0.6 mg% i patients with neoplasms, and 0.05 ± 0.004 mg% in healthy controls. The BDG content was the most useful in distinguishing jaundice associated with neoplasms (8.49 ± 0.9 mg%) from jaundice due to viral hepatitis (2.58 ± 5.3 mg%).

3426 DETECTION, BY THREE TECHNIQUES, OF HEPATITIS B SURFACE ANTIGEN (HBsAg) AND DETERMINATION OF HBsAg AND ANTI-HBs TITRES IN PATIENTS WITH CHRONIC LIVER DISEASE.

(Eng.) Chiaramonte, M.; Heathcote, J.; Crees, M.; Sherlock, S. (Clinica Medica 1, Univ. Padova, Padova, Italy). *Gut* 18(1): 1-6; 1977.

The sensitivities of three techniques used to detect serum hepatitis B surface antigen (HBsAg) were compared in 411 patients with chronic liver disease. Counterimmunoelectrophoresis was an unreliable test as only HBsAg titers exceeding 1:256 could be detected. Two hemagglutination techniques were slightly less sensitive than radioimmunoassay, but were more rapidly performed. Less sensitive techniques were particularly unreliable in active liver disease where HBsAg titers were low. HBsAg was detected in patients with chronic persistent hepatitis, alcoholic liver disease, chronic active liver disease with or without cirrhosis, and primary liver cell carcinoma. Forty-six of the 68 (68%) HBsAg-positive subjects were males coming from outside the United Kingdom. The HBsAg titers in 13 subjects with chronic persistent hepatitis were significantly higher ($p<0.001$) than those in 43 subjects with chronic active liver disease. Corticosteroid therapy did not alter the HBsAg titer significantly. None of the 28 HBsAg-positive subjects studied serially for up to 2 yr cleared HBsAg from the serum. Antibody to HBsAg (anti-HBs), analyzed by passive hemagglutination, was found in 35 subjects, 26 of whom had no evidence of liver disease; 80% came from abroad. Anti-HBs was believed to be of epidemiological rather than of pathological importance.

3427 CELL-MEDIATED IMMUNITY IN HEPATITIS B INFECTION.

(Eng.) Galbraith, R. M. (King's Coll. Hosp., London, England). *Minerva Gastroenterol.* 22(3):233-234; 1976.

A brief review of factors contributing to the hypothesis that the degree of liver damage resulting from hepatitis B infection is related to the immune response to the viral antigens is presented. The existence of perfectly healthy individuals with large amounts of hepatitis B surface antigen both in the liver and in the serum, but with no detectable liver disease, makes it unlikely that the hepatitis B virus is directly cytopathogenic.

28 FAILURE OF SPECIFIC IMMUNOTHERAPY IN FULMINANT TYPE B HEPATITIS. (Eng.) Acute

patic Failure Study Group. (Univ. Southern Califor-
a Sch. Medicine, Los Angeles, CA 90007). *Ann.*
tern. Med. 86(3):272-277; 1977.

i.v. hepatitis B immune globulin preparation for
e treatment of fulminant type B hepatitis was eval-
ted in 53 patients. Hepatitis B surface antigen-
sitive patients were treated at stage II to stage
of hepatic encephalopathy. A central computer
ogram randomized cases for treatment with hyper-
mune globulin or albumin placebo. During the
rst 6 months, the dose of hepatitis B immune glob-
in was 1.32 g of immunoglobulin G protein; during
e last 7 months, it was 5.28 g. Neither dose
iminated antigenemia. In the placebo group, death
curred in 4 of 8 cases randomized at stage II, 5
8 at stage III, and 10 of 12 at stage IV. In the
oup treated with hyperimmune globulin, death
curred in 3 of 5 patients randomized at stage II,
of 12 at stage III, and 6 of 8 at stage IV. The
sults suggest that administration of exogenous
tibody is not beneficial in the treatment of ful-
nant type B hepatitis.

29 RELEASE OF e ANTIGEN FROM A DANE PARTICLE-RICH PREPARATION OF HEPATITIS B VIRUS.

ng.) Lam, K. C.; Tong, M. J.; Rakela, J. (Univ.
uthern California Sch. Medicine, Downey, CA 90242).
fect. Immun. 16(1):403-404; 1977.

e suggestion that the e antigen (HBeAg) and DNA
lymerase activity may be identical was tested by
yering portions of sera from a patient with cir-
lating hepatitis B surface antigen (HBsAg), HBeAg,
ne particles, and DNA polymerase activity onto 30%
crose and centrifuging them at 230,000 x *g*. The
crose fractions contained HBsAg and HBeAg, but were
void of significant DNA polymerase activity; the
eAg and HBsAg were subsequently separated by affin-
y chromatography. Although HBeAg were not found
Dane-rich pellets that had been resuspended in
osphate-buffered saline, treatment of the pellets
th Tween 80 resulted in the appearance of detec-
ble HBeAg, as well as an increase in DNA polymer-
e activity. HBeAg was not detected in similarly
eated sera obtained from three HBsAg-positive pa-
ents that originally contained Dane particles,
t were HBeAg-negative and devoid of DNA polymerase
tivity. This may indicate defective HBeAg synthe-
s by the hepatocyte, resulting in the production
incomplete viral particles. If so, the presence
circulating HBeAg may represent the formation of
mplete virions and may indicate potential hepatitis
virus infectivity.

30 CORRELATIONS BETWEEN THE DETECTION OF e ANTIGEN OR ANTIBODY AND ELECTRON MICRO-
OPIC PATTERN OF HEPATITIS B SURFACE ANTIGEN (HBsAg)
SOCIATED PARTICLES IN THE SERUM OF HBsAg CARRIERS.

ng.) Trepo, C.; Bird, R. G.; Zuckerman, A. J.
avillon H, Hopital Edouard-Herriot, 69374 Lyon
dex 2, France). *J. Clin. Pathol.* 30(3):216-220;
77.

To investigate further the clinical significance of the e antigen/antibody system and its relation with hepatitis B surface antigen (HBsAg)-associated particles, the distribution of HBsAg associated particles, especially the presence of Dane particles, was studied by electron microscopy in coded sera of 68 chronic HBsAg carriers. The results were correlated with the detection of antigen (eAg) or antibody (eAb) and with clinical diagnosis. Sera from hemodialysis and chronic hepatitis patients showed a high prevalence of e antigenemia (9/13, 69.2% and 8/19, 42.1%, resp.) and Dane particles (11 and 16 resp., 84%). By contrast, out of 36 chronic asymptomatic carriers of HBsAg, 28 (77.7%) were positive for eAb, but only 1 (2.7%) had eAg. Dane particles were found in 13/36 (36.1%). A statistically significant correlation was observed between the detection of eAg and the presence of Dane particles (94.4%) in the serum. However, Dane particles were still observed in 10 of 28 (35.7%) anti-e positive sera. The data suggest that eAg may be linked to complete hepatitis B virions.

3431 A COMPARATIVE STUDY OF HEPATITIS B AND NON-B IN HOSPITALIZED ADULTS IN AN ENDEMIC AREA.

(Eng.) Krausz, Y.; Melamed, S.; Sandler, S. G.; Eliakim, M. (Hadassah Univ. Hosp., Jerusalem, Israel). *Isr. J. Med. Sci.* 13(1):9-14; 1977.

The epidemiologic, clinical, and laboratory features of 40 adults with acute viral hepatitis B were compared with those of 40 adults with non-B hepatitis. The clinical course of hepatitis B tended to be more severe than that of non-B hepatitis. Fever was significantly more common in hepatitis B (80% of cases) than in non-B hepatitis. Hepatitis B was also associated with more extensive liver injury (i.e., mean SGOT=3,042 ± 353 mU/ml, mean hospital stay=14.4 ± 2.2 days) than with non-B hepatitis (mean SGOT=1,861 ± 273 mU/ml, hospital stay=11.3 ± 0.9 days). No significant differences were noted in mean values for alkaline phosphatase, albumin, globulin, and cholesterol or for prothrombin activity. There were no significant differences between hepatitis B and non-B with regard to possible acquisition of infection by contaminated materials during dental treatment, by needle injections, or by other modes of parenteral exposure, except for blood transfusion. The mean age of patients with hepatitis non-B was significantly lower (23.3 yr) than that of patients with hepatitis B (32.7 yr). Blood transfusion during the previous 6 months was significantly correlated with hepatitis B, being a probable etiologic factor in 30% of the cases; none of the non-B hepatitis patients had received a blood transfusion within the previous 6 months ($p<0.05$). Sixty-three percent of the patients with hepatitis B and 53% of the patients with non-B hepatitis presented during June-October. The clinical findings confirm the view that hepatitis B is characteristically more insidious in onset, more severe in clinical course, and more prolonged in duration than non-B hepatitis.

3432 NON-B HEPATITIS IN MELBOURNE: A SEROLOGICAL STUDY OF HEPATITIS A VIRUS INFECTION.

(Eng.) Gust, I. D.; Dienstag, J. L.; Purcell, R.

H.; Lucas, C. R. (Fairfield Hosp. Communicable Diseases, Melbourne 3078, Australia). *Br. Med. J.* 1(6055):193-195; 1977.

The value of immune adherence hemagglutination tests for antibody to hepatitis A virus in the diagnosis of non-B hepatitis was studied in 16 patients from six families in which two or more cases of hepatitis had occurred within 3 months, in 8 patients with hepatitis with no known source of infection, and in 2 parenteral drug abusers, both of whom had had two attacks of acute hepatitis. The diagnosis of hepatitis A was confirmed by seroconversions or significant rises in hepatitis A antibody titers in 14 patients in the first group, 7 in the second group, and 1 of the two attacks of each non-B hepatitis patient in group 3. The case reports of the four patients in whom attacks of hepatitis lacked serological confirmation are presented. In patients with acute hepatitis A, antibody detectable by immune adherence hemagglutination became detectable 3-4 weeks after the onset of symptoms and reached a peak about 5 weeks later. The results confirm that the detection of rising hepatitis A antibody titers by immune adherence hemagglutination is a reliable index of infection with hepatitis A virus. The presence of a high hepatitis A antibody titer during the first 2 weeks of illness, or its absence in sera collected 6 weeks or more after the onset of symptoms, makes a diagnosis of hepatitis A unlikely.

3433 A PROSPECTIVE STUDY OF ACUTE VIRAL HEPATITIS WITH PARTICULAR REFERENCE TO HEPATITIS A. (Eng.) Locarnini, S. A.; Gust, I. D.; Ferris, A. A; Stott, A. C.; Wong, M. L. (Alfred Hosp., Melbourne, Victoria, 3181, Australia). *Bull. WHO* 54(2): 199-206; 1976.

To investigate the relationship of hepatitis A antigen to viral hepatitis, a prospective study was carried out on 97 patients with suspected viral hepatitis, and 3 of their family contacts. Evidence of infection with hepatitis A virus was obtained by detecting hepatitis A antigen in stools, and/or antibody to it in sera, by immune electron microscopy. Infection with hepatitis B virus was determined by testing for hepatitis B surface antigen and antibody in serum, by solid phase radioimmunoassay. Sixteen patients had diseases other than viral hepatitis and two patients (child contacts) suffered no illness. There was clinical and/or biochemical evidence compatible with viral hepatitis in 82 patients, of whom 35 had confirmed hepatitis A and 31 had hepatitis B. In the remaining 16 patients, there was no evidence of infection with either hepatitis A or B virus. It is possible that some of these patients may have been infected with viral agents as yet unidentified.

3434 DEVELOPMENT OF CHRONIC LIVER DISEASE AFTER ACUTE NON-A, NON-B POST-TRANSFUSION HEPATITIS. ROLE OF γ-GLOBULIN PROPHYLAXIS IN ITS PREVENTION. (Eng.) Knodell, R. G.; Conrad, M. E.; Ishak, K. G. (Univ. New Mexico Sch. Medicine, Albuquerque, NM 87131). *Gastroenterology* 72(5, Part 1): 902-909; 1977.

The occurrence of chronic liver disease after acute non-A, non-B post-transfusion hepatitis is documented, and the clinical course, risk factors, and hepatic lesions seen in 44 cases are characterized. Ten cases of chronic liver disease were identified in the 44 cases of acute non-A, non-B post-transfusion hepatitis. Age, sex, severity of acute illness, and prevalence of preoperative antibodies to known hepatitis-producing agents did not differ between the group whose hepatitis progressed to chronicity and the group whose hepatitis resolved. Less progression of acute hepatitis to chronic liver disease was seen in those patients receiving immune serum globulin preoperatively than in those receiving an albumin placebo ($p=0.009$). Only three patients had clinical symptoms of hepatitis at the time of liver biopsy, and elevations of liver enzymes and γ-globulin were mild. However, liver biopsy specimens in 8 of 10 patients showed chronic active hepatitis, and an additional biopsy specimen showed cirrhosis. Acute non-A, non-B post-transfusion hepatitis often progresses to chronic active hepatitis; preoperative γ-globulin prophylaxis significantly reduces this progression. Identification and characterization of this viral agent(s) will further aid in the prevention of this undesirable complication of blood transfusion.

3435 SIGNIFICANCE OF DETERMINATION OF THE ENZYMES AND ISOENZYMES ACTIVITY FOR DIAGNOSIS OF ACUTE NECROSIS OF THE LIVER (IN VIRAL HEPATITIS). (Rus.) Drobinsky, I. R.; Andriutsa, K. A.; Gabarets, E. P. (Kishinev Medical Inst., Kishinev, USSR). *Klin. Med. (Mosk.)* 54(11):39-44; 1976.

LIVER AND BILIARY TRACT

Chronic Hepatitis

51 GENETIC FACTORS IN THE DEVELOPMENT OF CHRONIC ACTIVE HEPATITIS. (Eng.)
ndberg, J.; Lindholm, A.; Iwarson, S. (East
sp., Univ. Goteborg, Goteborg, Sweden). *Lancet*
8002):67-68; 1977.

e occurrence of triggering agents and the fre-
ency of autoantibodies were studied at the on-
t of symptoms in 41 chronic active hepatitis
AH) patients with histocompatibility antigens
A-B8 and B12 and in patients with other HLA types.
enty-five patients had HLA-B8 and/or B12. In 11 of these patients (44%), a possible triggering factor was present; 5 patients had histological and/or serological signs of viral hepatitis and 6 had a history of drug exposure. In contrast, in 14 of the 16 patients without HLA-B8 or HLA-B12 (88%), a possible triggering factor was shown to be associated with the onset of symptoms ($p<0.02$). Antinuclear antibodies (ANA) were found in 68%, and smooth muscle antibodies (SMA) in 52%, of the patients with HLA-B8/12; in patients with other HLA-types, the corresponding frequencies were 43% and 50%. ANA was present in 36% of the

HLA-B8/12 patients in whom CAH could have been triggered by external agents and in 93% of the HLA-B8/12 patients with cryptogenic CAH ($p<0.01$). No such difference was observed in the frequency of SMA (45% and 57%, resp.) in these two groups. The results suggest that there are at least two pathogenetically different types of CAH--one genetically determined type in which no external factor is involved and in which autoimmune phenomena are common, and another type triggered by environmental agents.

3452 CIRCULATING T AND B LYMPHOCYTES AND IMMUNOGLOBULIN CONTAINING CELLS IN THE LIVER IN CHRONIC ACTIVE LIVER DISEASE.

(Eng.) Aldershvile, J.; Dietrichson, O.; Hardt, F.; Nielsen, J. O. (Kommunehospitalet, DK-1399 Copenhagen K, Denmark). *Acta Pathol. Microbiol. Scand. [C]* 85(1):26-32; 1977.

The numbers of circulating thymus-derived and bone marrow-derived lymphocytes (T and B lymphocytes) were compared in 25 patients with biopsy-verified hepatitis B surface antigen (HBsAg)-positive and -negative chronic nonalcoholic liver disease. Fifteen patients had circulating HBsAg and/or anti-HBsAg, and 10 were without these markers. In both groups of patients, a significant decrease of T cells and a parallel significant increase in null cells was found, but no difference with respect to T and null cells in patients in the two groups was observed. Liver biopsies from five patients with and four without HBsAg and/or anti-HBsAg were studied for the presence of immunoglobulin-bearing cells. In three of five liver biopsies from the HBsAg- and/or antibody-positive patients and in two of the four liver biopsies from the HBsAg- and anti-HBsAg-negative patients, a heavy periportal infiltration with plasma cells was found. However, the number and classes of the immunoglobulin containing cells could not be correlated either to the histological evaluation of the stage of activity of the liver disease or to the markers for HB virus infection. The immunological findings in the two groups of patients with chronic liver disease seem to be of the same nature and are most likely a consequence of the liver disease.

3453 HLA DETERMINANTS IN CHRONIC ACTIVE LIVER DISEASE: POSSIBLE RELATION OF HLA-Dw3 TO PROGNOSIS.

(Eng.) Opelz, G.; Vogten, A. J. M.; Summerskill, W. H. J.; Schalm, S. W.; Terasaki, P. I. (Sch. Medicine, Univ. California, Los Angeles, CA 90024). *Tissue Antigens* 9(1):36-40; 1977.

Sixteen alleles of the histocompatibility antigen (HLA) locus A and 18 alleles of locus B, as well as the locus D antigen HLA-Dw3, were examined in 38 patients with severe chronic active liver disease (CALD). HLA typing was carried out by the standard microcytotoxicity technique, using 120 antisera. The frequency of HLA-Dw3 was significantly more frequent in the CALD patients (68%) than in 91 controls (24%, $p<0.0001$). Thirteen of 25 HLA-B8-negative patients gave typing reactions with Dw3 (52%), in contrast to 8 of 69 (12%) of the B8-negative controls ($p<0.001$). Sixteen of 26 patients with Dw3 had cirrhosis and/or were treatment failures, compared to only 3 of 12 patients without Dw3, and a longer duration of treatment with steroids (23 months) was required in those with Dw3 than in those without (13 months). The data show that the association of CALD with HLA-Dw3 is significantly stronger than the association with HLA-B8, implying genetic control of CALD by a locus in the proximity of the D locus of the HLA chromosome. It is suggested that genetic factors influence both susceptibility to CALD and response to treatment.

3454 PREDNISONE FOR CHRONIC ACTIVE LIVER DISEASE: PHARMACOKINETICS, INCLUDING CONVER SION TO PREDNISOLONE.

(Eng.) Schalm, S. W.; Summe kill, W. H. J.; Go, V. L. W. (Univ. Hosp., Dijkzigt Rotterdam, Netherlands). *Gastroenterology* 75(5, Pa 1):910-913; 1977.

To determine the effect of impaired liver function on conversion of prednisone to prednisolone, and tc investigate the relationship of this to responses to treatment with prednisone, serum prednisone and prednisolone were measured by radioimmunoassay afte the i.v. injection of prednisone (10 mg). The subjects included 10 healthy volunteers, 6 untreated patients with severe chronic active liver disease (CALD), 10 patients with prednisone-induced remiss of CALD, and 3 patients with CALD deteriorating despite treatment with prednisone. Prednisone disappearance was comparable in all groups, and substa tial values for serum prednisolone appeared in all groups within 0.3 hr. Minor differences between tl groups included lower than normal serum prednisolor in severe CALD and treatment failure, a higher percentage of nonprotein bound prednisolone in such pa tients, and an association between earlier treatme with prednisone and an increased disappearance rat of prednisolone. No major defect of prednisone metabolism occurs in CALD, and failure of this condition to respond to therapy with prednisone is caused by other factors.

3455 WHAT ABOUT CHRONIC ACTIVE HEPATITIS TODAY?

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

3458 SEX-RELATED DIFFERENCES AMONG 100 PATIENTS WITH ALCOHOLIC LIVER DISEASE. (Eng.) Morgan, M. Y.; Sherlock, S. (Royal Free Hosp., London NW3 2QG, England). *Br. Med. J.* 1(6066):939-941; 1977.

The drinking patterns, presentation, clinical picture, and prognosis in 77 men and 23 women with a history of alcohol abuse and abnormal liver function test results were studied to determine whether sex differences are present in alcoholic liver disease. On presentation, the women were less likely to be suspected of alcohol abuse (38%) than the men (77%). Although the quantity of alcohol consumed and length of history of alcohol abuse were similar for men and women, the incidence of chronic advanced liver disease was higher among women (86%) than among men (65%). However, women were less likely than men to have developed primary liver cell cancer. Overall, the women had a higher incidence of other alcohol-related disorders and were less likely to stop abusing alcohol (9%) than were their male counterparts (29%). Women seem to be more susceptible to alcohol-related disease.

3459 ALCOHOLICS IN A PSYCHIATRIC ENVIRONMENT. CLINICAL, DIETETIC, BIOLOGICAL AND HISTOLOGICAL CHARACTERISTICS IN RELATION TO ALCOHOL CONSUMPTION. (Fre.) Clermont, R. J.; Pelletier, G.; Desrochers-Gauthier, S. (Hotel-Dieu de Montreal, 3840, Rue St-Urbain, Montreal, Quebec, H2W 1T8, Canada). *Rev. Fr. Gastroenterol.* (116):7-20; 1976.

Clinical, histological, and dietary profiles were obtained for 65 alcoholic patients admitted to a psychiatric hospital in a 1-yr period. Clinical symptoms were usually gastrointestinal (vomiting, abdominal pain, 45%; diarrhea, 68%); only 18% demonstrated delirium tremens. Radiology revealed gastrointestinal abnormalities in 72% of patients (gastritis, 34%; esophagitis, 23%; and ulcers, 39%). Sixty-three percent of patients had elevated alkaline phosphatase, 72% had abnormal SGOT, and 40% had elevated uric acid levels. Liver biopsies performed on 49 patients showed abnormal pathology (inflammation, fibrosis, steatoses, focal necrosis) in 95%. When blood studies were related to liver biopsies, the values of SGOT and alkaline phosphatase were more likely to be abnormal in patients with moderate rather than advanced cirrhosis. The dietary profiles obtained on 48 patients showed an average daily caloric intake of 2,815 calories (841-5,192), 44% of which was from alcohol and 9% from protein. The type of alcohol used had an effect on the degree of cirrhotic pathology; however, quantity of alcohol, proportion of alcohol in total calorie intake, and protein intake had no relation to severity of cirrhotic disease.

3460 SIGNIFICANCE OF γ-GLUTAMYL TRANSFERASE (GGT) ACTIVITY MEASUREMENTS IN ALCOHOL-INDUCED HEPATIC INJURY. (Eng.) Boone, D. J.; Tietz, N. W.; Weinstock, A. (Univ. Kentucky Medical Center, Lexington, KY 40502). *Ann. Clin. Lab. Sci.* 7(1):25-28; 1977.

Serum samples from 64 patients who were heavy, steady, or spree drinkers were analyzed for γ-glutamyl transferase (GGT), alanine transaminase, aspartate transaminase, lactate dehydrogenase, and alkaline phosphatase activities, and experimental evidence that the determination of GGT is useful in the assessment of alcohol-induced liver disease is reviewed. A fivefold increase in mean GGT activity was observed in 81% of the 30 patients with a history of heavy alcohol intake; 72% of 14 steady drinkers (<a fifth of whiskey or wine/day) had a mean GGT value of approximately twice that of normal individuals, but spree drinkers showed no elevation in GGT activity. The determination of GGT activity was the most sensitive indicator of the amount of alcohol consumed. During the course of treatment, GGT activity decreased, regardless of the extent of the initial alcohol abuse. The determination of serum GGT is useful in the assessment of alcohol-induced liver disease and in demonstrating to patients the toxic effects of drinking habits on the liver.

3461 LYMPHOCYTE CYTOTOXICITY FOR ISOLATED HEPATOCYTES IN ALCOHOLIC LIVER DISEASE. (Eng.) Cochrane, A. M. G.; Moussouros, A.; Portmann, B.; McFarlane, I. G.; Thomson, A. D.; Eddleston, A. L. W. F.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, SE5, England). *Gastroenterology* 72(5, Part 1):918-923; 1977.

To determine whether an autoimmune reaction to liver-specific proteins occurs in alcoholic liver disease, the cytotoxic effect of lymphocytes on isolated hepatocytes was determined in 27 alcoholic patients. Cytotoxicity was demonstrated in 15 of 17 patients with a histological diagnosis of alcoholic hepatitis, but in none of 10 with other forms of alcoholic liver disease (cirrhosis without hepatitis, fatty liver, and minimal inflammatory changes). The ability of a liver-specific membrane lipoprotein to block the reaction suggests that sensitization to this antigen is responsible for the cytotoxicity. The demonstration of cytotoxicity using thymus-derived (T) cell-depleted, but not bone marrow-derived (B) and null (K) cell-depleted, lymphocytes suggests an antibody-dependent cell-mediated reaction. There was a close correlation between cytotoxicity and the presence of alcoholic hyalin, liver cell necrosis, and piecemeal necrosis, but not with other histological features, immunoglobulins, autoantibodies, or standard liver function tests. The persistence of this autoimmune response, induced in some way by alcohol or one of its metabolites, may be important in the progression of acute alcoholic hepatitis to chronic liver disease.

3462 CHRONIC FIBRINOLYSIS IN ALCOHOLIC CIRRHOSIS: THERAPEUTIC TRIAL WITH HEPARIN. (Fre.)

Thuot, C.; Marleau, D.; Viallet, A. (Hopital Saint-Luc, 1058 rue Saint-Denis, Montreal, Quebec H2X 3J4, Canada). *Rev. Fr. Gastroenterol.* (115):25-30; 1976.

Low doses of heparin (200 U/kg/24 hr, continuous i.v. infusion) were administered to eight patients with alcoholic cirrhosis to determine whether the fibrinolytic activity without bleeding observed in chronic alcoholics with cirrhosis could be explained by disseminated intravascular coagulation. Fibrinolysis disappeared during heparin infusion in two of eight patients, but reappeared within 48 hr of the cessation of therapy. No cryofibrinogen or soluble complexes were found; fibrinogen levels were normalized; platelets, factors V and VIII, and prothrombin factors were not significantly changed. Hemostasis indicators and fibrinolytic activity were not modified in the other six patients, even though two were given higher doses of heparin (500 U/kg/24 hr). The results support the hypothesis that a low-grade disseminated intravascular coagulation is related to spontaneous fibrinolysis in chronic alcoholic cirrhotics.

3463 SCLEROSING HYALINE NECROSIS IN NONCIRRHOTIC CHRONIC ALCOHOLIC HEPATITIS. (Eng.)

Karasawa, T.; Chedid, A. (Univ. Cincinnati Sch. Medicine, Cincinnati, OH 45267). *Am. J. Clin. Pathol.* 66(5):802-809; 1976.

The clinical and morphological features in 18 chronic alcoholic patients with sclerosing hyalin necrosis in noncirrhotic livers were compared with those of 12 similar individuals with acute alcoholic hepatitis, but no centrilobular fibrosis. In cases with sclerosing hyalin necrosis, the most characteristic features were portal hypertension with very large, tender livers and unusually high GOT values; these were associated with centrilobular fibrosis and abundant alcoholi hyalin. Three of these patients died within 2 yr, an in two of these, early cirrhosis was found at autopsy. In the cases of acute alcoholic hepatitis, hepatomegal was the most conspicuous finding, and only a single patient died; death was unrelated to hepatic disease, th liver being unremarkable at autopsy. Patients who ha sclerosing hyalin necrosis tended to remain ill for significantly longer periods. These observations, in conjunction with evidence gathered from the literature suggest that sclerosing hyalin necrosis is an obligatory step in the natural evolution of alcoholic hepati disease, especially in cases that evolve into cirrhosi

3464 ABNORMAL PLASMA LIPOPROTEINS AND LECITHIN-CHOLESTEROL ACYLTRANSFERASE DEFICIENCY IN ALCOHOLIC LIVER DISEASE. (Eng.)

Sabesin, S. M.; Hawkins, H. L.; Kuiken, L.; Ragland, J. B. (Univ. Tennessee, Coll. Medicine, 951 Court Ave., Memphis, TN 38163). *Gastroenterology* 72(3):510-518; 1977.

Serial studies of plasma lipids and lipoproteins were performed in four patients with acute alcoholic liver disease characterized by a massive fatty liver and intrahepatic cholestasis. There were striking alterations in the plasma lipoprotein electrophoretic patterns characterized by the absence of α- and pre-β-lipoprotein bands and the presence of a single band of abnormal mobility. An extreme associated decrease in plasma lecithin-cholesterol acyltransferase activity resulted in greatly reduced levels of plasma cholesteryl esters and increased levels of unesterified cholesterol. In two patients, hypertriglyceridemia and hypercholesterolemia were present, the latter because of an increase in unesterified cholesterol. Lipoproteins were isolated from the plasma by sequential ultracentrifugation at the densities used for separation of normal very low density, low density, and high density lipoproteins; however, the patients' lipoproteins were different from normal in lipid composition and ultrastructure. All of the lipoprotein fractions were decreased in cholesteryl esters, and the major lipoprotein was a triglyceride-rich low density lipoprotein. Ultrastructural studies of the low and high density lipoprotein fractions revealed the presence of bilamellar vesicles and stacked discs. All changes in lipoprotein composition and ultrastructure gradually returned to normal with clinical improvement. These observations indicate that alcoholic liver injury is associated with profound alterations in lipoprotein composition and metabolism, and may be related, in part, to lecithin-cholesterol acyltransferase deficiency.

3465 FROM DRINKING TO CIRRHOSIS. (Fre.)

Thomas, M. (Hopital Saint-Antoine, 184, rue du Faubourg, Saint-Antoine, 75012 Paris, France). *Rev. Prat.* 26(51):3559-3568; 1976.

LIVER AND BILIARY TRACT

Cirrhosis

67 A DIAGNOSTIC TRIAD FOR PORTAL CIRRHOSIS. (Eng.) Goldberg, D. M.; Ellis, G.;
rd, A. M. (Hosp. Sick Children, 555 University Ave.,
ronto, Ontario M5G 1X8, Canada). *Clin. Chim.*
ta 72(3):379-382; 1976.

triad of clinical abnormalities commonly en-
untered in portal cirrhosis is described. The
sults of various tests in 49 patients with por-
l cirrhosis were compared with those from 19
tients with cholelithiasis, 18 patients with
flammatory disease of the gallbladder or bile
cts, 19 patients with carcinoma of the head of
e pancreas, 10 patients with bile duct car-
noma, 11 patients with chronic active hepatitis,
patients with viral hepatitis, 13 patients with
imary biliary cirrhosis, 32 patients with hepa-
c metastases, and 5 patients with postnecrotic
rrhosis. Abnormal serum aminotransferase act-
ities, with dominance of aspartate aminotrans-
rase over alanine aminotransferase activity,
l elevated serum adenosine deaminase activity
l IgA concentration, were commonly encountered
ong the patients with portal cirrhosis. The
ll triad was present in 31 of the 49 cases
3%). As isolated abnormalities, these features
re not uncommon in patients with other diseases
the liver and biliary tree, but the full triad
s found in only 11 of 163 such cases (6.8%).
e presence of this triad in a patient with un-
plained hepatomegaly is indicative of portal
rrhosis.

8 SPECIFIC FEATURES OF THE CLINICAL COURSE OF BILIARY CIRRHOSIS OF THE LIVER. (Rus.)
inov, A. S.; Yartseva, H. M.; Kryukova, L. V.;
chak, S. N. (Central Scientific-Res. Inst.
troenterology, Moscow, USSR). *Ter. Arkh.*
9):12-20; 1976.

e clinical, morphological, immunological, and
ctional features of primary biliary cirrhosis
re studied in 90 patients with cholestatic hepa-
is (CH) and primary biliary cirrhosis (PBC).
all patients, diagnosis was confirmed at morpho-
ical examination (laparoscopy, laparotomy); all
10 patients were subjected to biopsy. Transforma-
n of CH into PBC was observed in 15 patients subjec-
l to long-term follow-up. Two stages of CH, which
ceeded the PBC, could be recognized. The patients
h stage I (anicteric) CH complained of pruritus, xanthelasma, and arthralgia; they had elevated serum cholesterol, bile acids, transaminases, and alkaline phosphatase. Hepatitis symptoms were more pronounced in the patients with stage II of CH; all patients had enlargement of the liver. The patients with stages II and III (PBC) showed enlargement of lymph nodes and changes in the mucosa of the stomach and duodenum; 12 patients had duodenitis, 15 erosive or atrophic gastritis, and 15 duodenal ulcer; 15 patients had pulmonary syndrome. Forty-five patients with PBC had endocrine disturbances, 5 patients had cyst of the appendages, and 8 had fibromyoma of the uterus.

3469 A CONTROLLED TRIAL OF D-PENICILLAMINE THERAPY IN PRIMARY BILIARY CIRRHOSIS. (Eng.)
Jain, S.; Scheuer, P. J.; Samourian, S.; McGee, J. O.; Sherlock, S. (Royal Free Hosp., Pond St., London NW3 2QG, England). *Lancet* 1(8016):831-834; 1977.

The value of D-penicillamine (900 mg, daily) therapy in primary biliary cirrhosis was studied in a randomized controlled trial. Nineteen patients received D-penicillamine, and 13 received placebo. The two groups were similar in age, duration of illness, liver function tests, and liver histology. Before entry into the trial the liver-copper concentration was raised in 25 of the 27 patients in whom it was measured. After 3 months, patients taking D-penicillamine showed a significant reduction in serum-aspartate-transaminase concentrations, compared with the placebo group, and this reduction seemed to be sustained. In the four patients on D-penicillamine for a year, a second liver biopsy showed that mean liver-copper concentration fell from 310 ± 128 to 84 ± 36 μg/g dry liver, compared with a reduction from 511 ± 169 to 454 ± 128 in the seven patients in the placebo group in whom serial liver-copper measurements were available. Liver histology demonstrated a comparative improvement in cholestasis in patients on penicillamine, but the degree of inflammation, necrosis, and the histological stage of disease remained similar in both groups. The drug was discontinued because of side-effects (i.e., nausea and vomiting, urticaria, proteinuria) in 5 of the 19 patients in the D-penicillamine group. One patient who developed erythromyeloid aplasia with septicemia recovered after antibiotics and WBC infusions. D-penicillamine seems to be a promising treatment for patients with primary biliary cirrhosis. It may produce its effect by reducing liver copper concentration.

3470 THE ARTERIAL BLOOD SUPPLY TO THE LIVER IN CIRRHOSIS. (Eng.) Baer, J. W. (St. Luke's Hosp. Center, Amsterdam Ave. at 114th St., New York, NY 10025). *Gastrointest. Radiol.* 1(3):209-213; 1976.

A retrospective study of celiac and superior mesenteric arteriograms in 21 cirrhotic and 27 noncirrhotic patients was carried out to establish the incidence and significance of collateral circulation to the liver from the superior mesenteric artery. Nine cirrhotic patients had collateral arterial flow. In four of these patients, celiac angiography demonstrated forward flow in the gastroduodenal artery, but superior mesenteric arteriography showed some retrograde flow through the gastroduodenal artery to the hepatic artery distal to the origin of the gastroduodenal artery. In the remaining five patients, a celiac injection demonstrated no filling of the gastroduodenal artery; a concave filling defect was noted in the inferior aspect of the main hepatic artery at the site of origin of the gastroduodenal artery. The superior mesenteric arteriogram showed filling of the hepatic arteries distal to the gastroduodenal artery origin throughout the gastroduodenal arcade, and there was no visualization of the main hepatic artery. Two patients with the former type of collateral flow and three patients with the latter type had evidence of centrifugal portal flow, as measured by the presence of collateral venous flow. The degree of collateral arterial flow was also related to the presence of hyperbilirubinemia and the presence of a markedly enlarged spleen with increased splenic blood flow. Of the 27 noncirrhotic patients, 6 had collateral arterial flow to the liver from the superior mesenteric artery. The greatest degree of collateral arterial flow was associated with celiac stenosis in four of the six patients.

3471 A STUDY OF THROMBOCYTIC (MICROCIRCULATORY) HEMOSTASIS IN LIVER CIRRHOSIS. (Rus.) Makarevich, Ya. A.; Kosterova, V. V.; Podobedov, G. M.; Shamshev, V. M. (Astrakhan Medical Inst., Astrakhan, USSR). *Sov. Med.* (8):69-74; 1976.

Thrombocytic hemostasis was studied in 65 liver cirrhosis patients. Thrombocyte adhesion and aggregation were analyzed in the peripheral blood; in 19 patients, the indices were determined simultaneously in the peripheral and portal blood. The average adhesion of the peripheral thrombocytes in the patients with cirrhosis was lower than in healthy controls (28.4% and 33.7%, resp.); adhesion was more pronounced in the patients with postnecrotic cirrhosis (30.6%) than in patients with portal cirrhosis (27.2%). The average adhesion in the portal blood was significantly higher (38.2%) than in peripheral blood. Disaggregation of thrombocyte aggregates was significantly accelerated in the peripheral blood (46.3%, compared to 33.6% in controls) and reduced in the portal blood; the difference between the disaggregation in the peripheral and portal blood was most pronounced in 19 patients with hemorrhagic syndrome (81.0% and 33.9%, resp.).

3472 IN VIVO LABELING OF PLATELETS WITH ^{75}Se--SELENOMETHIONINE IN PATIENTS WITH HEPATIC CIRRHOSIS AND THROMBOCYTOPENIA. (Eng.) Mayer, M.; Herrmann, I.; Kempgens, U.; Queisser, W. (First Dept. Internal Medicine, Univ. Heidelberg, Heidelberg, W. Germany). *Thromb. Haemostas.* 37(1):47-52; 1977.

The platelets of nine patients with liver cirrhosis and thrombocytopenia were labeled *in vivo* with ^{75}Se-selenomethionine (^{75}Se-M) to evaluate the kinetics of platelet maturation in hepatic cirrhosis. Folic acid and vitamin B_{12} deficiency was excluded by pretreatment of the patients with these agents. The platelet maturation time (time between the injection of the isotope and maximum radioactivity of separated blood platelets) was shortened to 7.7 ± 1.1 days, compared to 9.1 ± 1.4 days in controls. A disturbance in megakaryocyte maturation and/or platelet release from the bone marrow is suggested in hepatic cirrhosis.

3473 THROMBIN TIME PROLONGATION IN CIRRHOSIS IN RELATION TO ENHANCED FIBRINOGEN DEGRADATION. (Eng.) Lipinski, B.; Gurewich, V.; Lipinska, I. (Tufts Univ. Sch. Medicine, Boston, MA 02135). *Thromb. Res.* 10(1):185-187; 1977.

The hypothesis that the prolonged thrombin time in the plasma of patients with liver disease is related to an abnormal fibrinogen level was investigated using 3.5% sodium dodecyl sulfate-polyacrylamide gel electrophoresis of the plasma and sera of healthy subjects and cirrhotic patients. Fibrinogen in normal plasma was found to be composed of a high molecular weight (HMW) and a lower molecular weight (LMW) fraction in a proportion of about 2:1. In an occasional healthy subject, a very low concentration of a still lower molecular weight band (LMW^1) was seen. In the cirrhotic patients, most, and in two cases all, of their fibrinogen migrated in the region of the LMW or LMW^1 bands. This may account for the prolonged thrombin time in these patients.

3474 LOWER ESOPHAGEAL SPHINCTER PRESSURE IN CIRRHOTIC MEN WITH ASCITES: BEFORE AND AFTER DIURESIS. (Eng.) Van Thiel, D. H.; Stremple, J. F. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *Gastroenterology* 72(5, Part 1):842-844; 1977.

Lower esophageal sphincter pressure (LESP) was measured in 10 biopsy-proved cirrhotics with esophageal varices and tense ascites before and after diuresis to evaluate the possibility that ascites play a role in the development of variceal bleeding. Basal LESP was 30.9 ± 1.7 mm Hg before and 22.7 ± 1.3 mm Hg ($p<0.01$) after diuresis, which resulted in a mean 12-kg weight loss. LESP responses to abdominal compression were also evaluated. The change in LESP in response to a standard degree of abdominal compreson (intragastric pressure increased 4 mm Hg) was eater in the presence of ascites (8.5 ± 0.4 mm Hg) an in its absence (6.3 ± 0.4 mm Hg, $p<0.01$). Basal stric pH and fasting plasma gastrin concentrations d not differ during the two testing periods. sed on these data and on the rarity with which rrhotic patients with ascites complain of heart- rn, it is concluded that reflux esophagitis caused failure of the lower esophageal sphincter to re- in competent is unlikely to be a significant etio- gical factor in the development of variceal bleed- g.

75 CORRELATION BETWEEN HEPATIC MORPHOLOGY AND IMMUNOGLOBULINS AND ANTIBODIES TO cherichia coli IN CIRRHOSIS.

(Eng.) Prytz, H.; orneboe, M.; Christoffersen, P.; Poulsen, H.; skov, F. (Bispebjerg Hosp., Copenhagen, Denmark). t 18(1):28-32; 1977.

e hypothesis that immunoglobulin and antibody vels in the serum of cirrhotic patients are re- ted to the degree of certain morphological changes the liver was tested. In 50 patients with cirrho- s, 28 alcoholics, and 22 nonalcoholics, the degree architectural destruction, the degree of fibrosis, e degree of fatty infiltration, and the degree of ctivity" were compared with immunoglobulins G, A, d M and *Escherichia coli* O antibody levels. The mparison was carried out within each etiological oup. Identical relationships were found in both oups. Patients with completely destroyed lobular chitecture had higher levels of *E. coli* O anti- dies than patients with partly destroyed archi- cture. Patients with severe fibrosis had higher A and *E. coli* O antibody levels than patients with derate or slight fibrosis. Patients with moderate d severe steatosis and patients with no or slight eatosis had the same immunoglobulin and *E. coli* antibody levels. Patients with active cirrhosis d higher IgG levels than patients with inactive rrhosis. When architectural destruction and brosis were combined, significantly higher IgG, A, IgM, and *E. coli* antibodies were found in the oup with the most severe changes. These findings pport the hypothesis that immunoglobulin and anti- dy levels are related to the degree of morpholog- al changes in the liver, i.e., destruction of lob- ar architecture, fibrosis, and "activity."

76 A NEW CASE OF MONOCLONAL IgA KAPPA COLD AGGLUTININ WITH ANTI-Pr_1d SPECIFICITY IN PATIENT WITH PERSISTENT HB ANTIGEN CIRRHOSIS.

ng.) Tonthat, H.; Rochant, H.; Henry, A. oorrier, M.; Dreyfus, B. (INSERM U-91, Hopital ri Mondor, F-94010 Creteil, France). *Vox Sang.* (6):464-468; 1976.

ew case of cold agglutinin disease in a 65-yr- d woman, who had a 7-yr history of Raynaud's enomenon without hemolysis and a persistent patitis B antigen cirrhosis, is reported. The tient's serum reacted with adult and cord cells a titer of 128. The cold agglutinin was a mono- onal IgA antibody that reacted at 4 C to a titer of 256. Treatment with 2-mercaptoethanol (0.1 M) reduced the titer to 8. Eluates, obtained after incubating the patient's serum with rat and dog cells, still reacted with human adult, cord, rat, and dog cells, but failed to react when these cells were treated with papain or neuraminidase, demonstrating characteristic Pr_1d specificity. The unique finding that this and three other IgA cold agglutinins described in the literature are all directed against the Pr_1 antigen indicates a strict correlation between antibody class and specificity.

3477 DIAGNOSTIC SIGNIFICANCE OF STUDIES OF PORPHYRINS IN DISEASES OF THE LIVER.

(Rus.) Makarevich, Ya. A.; Smporina, A. P. (Astrakhan Medical Inst., Astrakhan, USSR). *Ter. Arkh.* 48(9): 61-66; 1976.

The diagnostic value of porphyrin tests was studied in 60 patients with cirrhosis and 41 patients with porphyria cutanea tarda (urocoproporphyria). Of 41 patients with porphyria cutanea tarda, 23 had cirrhosis (13 patients had initial stage of active, portal cirrhosis, and 10 patients had stage II cirrhosis with mixed hepatocellular and vascular insufficiency), 10 had chronic hepatitis, and 8 did not have morphological changes in the liver. The patients with cirrhosis had elevated level of coproporphyrin in the urine (206 ± 20 µg/g, compared to 37.2 ± 4.7 µg/g in controls) and nonaltered levels of uroporphyrin (33 ± 4 µg/g, compared to 27.7 ± 4.2 µg/g in controls). The patients with porphyria cutanea tarda were found to have elevated level of coproporphyrin (378 ± 56 µg/g) and markedly elevated levels of uroporphyrin (2, 453 ± 279 µg/g). The coproporphyrin:uroporphyrin ratio was 6.2 in the patients with cirrhosis with symptomatic copro- porphyria and 0.1 in the patients with porphyria cutanea tarda.

3478 TOTAL AND FREE THYROXINE IN PATIENTS WITH LIVER CIRRHOSIS.

(Eng.) Gembicki, M.; Dzieciuchowicz, S.; Sowinski, J.; Makowska, K.; Klincewicz, H. (Klinika Endokrynologii, ul. Przybyszewskiego 49, 60-355 Poznan, Poland). *Pol. Med. Sci. Hist. Bull.* 15/4(2):213-216; 1976.

The total thyroxine serum concentration, the tri-iodothyronine-binding coefficient (T_3BC), free thyroxine (DFT_4), free thyroxine index (FT_4I), and absolute value of free thyroxine ($ADFT_4$) were determined in 11 patients with compensated liver cirrhosis, 10 patients with uncompensated cirrhosis, and 41 healthy controls, in an attempt to evaluate thyroid function in cirrhotic patients. In the uncompensated cirrhotic patients, the mean T_3BC (0.103 ± 0.047), FT_4I (0.76 ± 0.32), DFT_4 (0.046 ± 0.025%), and $ADFT_4$ (3.1 ng%) values were significantly elevated in comparison with those of the controls ($p<0.05$ for T_3BC, $ADFT_4$, and FT_4I; $p<0.01$ for DFT_4). The authors conclude that these changes are due to disturbances in the binding capacity of the proteins that bind thyroid hormones and also to an impaired degradation of these hormones in the liver.

3479 INTESTINAL ABSORPTION OF 25-HYDROXYVITAMIN D AND OSTEOMALACIA IN PRIMARY BILIARY CIRRHOSIS.

(Eng.) Compston, J. E.; Thompson, R. P. H. (St. Thomas' Hosp., London SE1, England). *Lancet* 1(8014):721-724; 1977.

Intestinal absorption of vitamin D was investigated in 11 patients with primary biliary cirrhosis to study the etiology of the osteomalacia sometimes seen in these patients. Bone biopsies revealed that four patients had severe osteomalacia, all of whom had been taking p.o. cholestyramine for over 2 yr; one patient without osteomalacia had been treated with cholestyramine for 3 months prior to the study. The mean plasma 25-hydroxyvitamin D (25-OHD) concentrations before and after a p.o. dose of 25-OHD$_3$ (10 μg/kg) were significantly lower in patients (7.1, 42.0, 45.1, and 30.2 ng/ml at 0, 4, 8, and 24 hr, resp.) than in 30 healthy controls (17.7, 124.6, 135.6, and 93.8 ng/ml at 0, 4, 8, and 24 hr, resp.). The mean plasma 25-OHD concentrations at 4, 8, and 24 hr were lower in the patients with osteomalacia than in the seven patients without, and at 4 and 8 hr, these differences were significant ($p<0.025$). The patient without osteomalacia who was taking cholestyramine had the lowest 25-OHD concentrations in the normal group. The mean serum calcium was 2.32 ± 0.05 mM in the patients with osteomalacia and 2.54 ± 0.07 mM in the patients without ($p<0.05$). The mean 24-hr urinary calcium excretion was 0.6 ± 0.5 mmol in the patients with osteomalacia and 3.8 ± 0.6 mmol in the patients without ($p<0.01$), and the mean serum alkaline phosphatase was 134.8 ± 20.8 King-Armstrong (KA) U/dl in the former patients and 53.4 ± 9.8 KAU in the latter patients ($p<0.01$). It is suggested that the absorption of 25-OHD undergoing enterohepatic circulation and of dietary vitamin D is reduced in patients with primary biliary cirrhosis. 25-OHD absorption is further decreased by cholestyramine, and the development of osteomalacia is hastened.

3480 REDUCED BINDING OF ADDED ZINC IN SERUM OF PATIENTS WITH DECOMPENSATED HEPATIC CIRRHOSIS.

(Eng.) Giroux, E.; Schechter, P. J.; Schoun, J.; Sjoerdsma, A. (Centre de Recherche Merrell International, 16 rue d'Ankara, 67000 Strasbourg, France). *Eur. J. Clin. Invest.* 7(1):71-73; 1977.

The possibility that the albumin of cirrhotic patients and of normal subjects differs in its affinity for zinc was examined in 13 decompensated cirrhotic patients and 12 healthy subjects. Binding of zinc to macromolecules when added to serum was measured by ultrafiltration. In 12 of the 13 patients, the total serum zinc concentration (497 ± 34 μg/l) was more than two standard deviations below the mean of the group of 12 normal subjects (924 ± 36 μg/l, $p<0.001$). All patients had significantly lower serum albumin and serum albumin-bound zinc concentrations (29 ± 2 μg/l and 312 ± 27 μg/l, resp.) than the controls (46 ± 1 μg/l, $p<0.001$ and 753 ± 31 μg/l, $p<0.001$, resp.). At a final ratio of 0.6 mol zinc/mol albumin, zinc dissociable by glycine was significantly greater in diluted serum from the patients than in normal serum samples similarly prepared ($p<0.001$). Low serum zinc concentrations, often observed in patients with alcoholic cirrhosis, may be related in part to a reduced affinity of plasma albumi for exchangeable zinc.

3481 AN OPTIMAL DIURETIC REGIMEN FOR CIRRHOTIC ASCITES. A CONTROLLED TRIAL EVALUATING SAFETY AND EFFICACY OF SPIRONOLACTONE AND FUROSEMIDE.

(Eng.) Fuller, R. K.; Khambatta, P. B.; Gobezie, G. C. (Cleveland Veterans Admin. Hosp., 10701 East Blvd., Cleveland, OH 44106). *JAMA* 237(10):972-975; 1977.

The safety and efficacy of a regimen combining diuretic therapy with strict sodium restriction in the treatment of cirrhotic ascites were evaluated in a controlled trial. Eighteen male patients without life-threatening complications of cirrhosis and without hyponatremia were studied. In the first part of the study (9 patients), it was demonstrated that a 6-day diuretic regimen (50 mg spironolactone, b.i.d.; 40 mg furosemide daily during the last 3 days) with dietary sodium restriction of 10 mEq/day is safe and more effective than sodium restriction alone. During the respective 6-day treatment period and subsequent 6-day period in which the patients received placebo while on a sodium-restricted diet, seven of the nine subjects lost more weight when they received diuretics than when they received placebo; the average weight loss on diuretics was 3.2 kg greater than with sodium restriction alone ($p<0.01$). The abdominal girth of seven of the nine subjects decreased an average of 3.1 cm more when they were treated with diuretics ($p<0.05$). The subjects excreted 42 mEq more sodium daily when they had received diuretics ($p<0.01$). In the second study, 6 days of diuretic therapy were compared with 9 days in nine patients. One patient was excluded due to the development of asterixis and mental confusion after 4 days of diuretic therapy. Among the eight remaining patients, therapy was safely extended to 9 days, with mobilization of significantly more fluid. Careful selection of subjects, use of diuretics in modest dosages for brief periods of time, and daily monitoring of subjects are important for the safe treatment of cirrhotic ascites with diuretics and rigid dietary sodium restriction.

3482 CHOLANGIOCARCINOMA ASSOCIATED WITH BILIARY CIRRHOSIS DUE TO CONGENITAL BILIARY ATRESIA.

(Eng.) Kulkarni, P. B.; Beatty, E. C., Jr. (Children's Mercy Hosp., 24th and Gillham Rd., Kansas City, MO 64108). *Am. J. Dis. Child.* 131(4):442-444; 1977.

The case report of an 11-yr-old girl with cholangiocellular carcinoma in association with biliary cirrhosis due to congenital biliary atresia is presented. An exploratory laparotomy and an operative cholangiogram at 3 months of age had confirmed the diagnosis of extrahepatic biliary atresia. A liver biopsy specimen taken at 6 months of age showed biliary cirrhosis. The subsequent clinical course was characterized by persistent moderate jaundice, anemia, malnutrition, rickets, pathologic fractures, and recurrent gastrointestinal bleeding. The presence of cholangiocellular carcinoma of the liver with advanced biliary cirrhosis was estab-

shed at an exploratory laparotomy 1 week before
ath. A review of the literature suggests that
e association between cirrhosis and primary liver
rcinoma in childhood may be more than coincidental.

83 UPPER GASTROINTESTINAL HAEMORRHAGE IN
HEPATIC CIRRHOSIS: CAUSES AND RELATION
HEPATIC FAILURE AND STRESS. (Eng.) Franco,
; Deporte, A.; Durandy, Y.; Bismuth, H.
nserm, Hopital Paul Brousse, 14 avenue Paul-
illant Couturier, 94800 Villejuif, France).
ncet 1(8005):218-220; 1977.

e sites of upper gastrointestinal bleeding
ong 85 cirrhotic patients were compared with
e degree of hepatic failure and the severity
associated diseases to determine why some
rrhotic patients bleed from varices and
hers from acute ulcers. Among the 84 act-
ely bleeding sources, esophagogastric var-
es (52.4%) and acute mucosal ulcers (40.5%)
re the most frequent causes of bleeding. In
e 56 patients with moderate or no hepatic
ilure, esophagogastric varices (62.5%), acute
ug-associated ulcers (21.4%), and chronic pep-
c ulcers (10.8%) were the main causes of bleed-
g. In the 28 patients with severe hepatic
ilure, acute drug-independent ulcers were the
mmonest lesions (60.7%), while ruptured esophago-
stric varices (32.1%) and acute drug-associated
cers (7.2%) were less frequent. Ruptured eso-
agogastric varices were significantly more
equent in patients with no or moderate liver
ilure (79.5%) than in patients with severe
ver failure (20.5%, $p<0.01$). Acute drug-
sociated ulcers were more frequent in the former
oup (85.7%) than in the latter (14.3%), al-
ough this difference was not significant.
ute drug-independent ulcers were significantly
re common in patients with severe liver failure
5%) than in the other group (15%, $p<0.001$).
ress factors were present in 7.1% of the 56
tients in whom hepatic failure was absent or
derate and in 43% of the 28 in whom it was
vere ($p<0.01$). In the severe hepatic failure
oup, stress was present in only 11% of the
tients in whom bleeding was due to esophago-
stric varices, but stress was present in 64%
the patients in whom bleeding resulted from
ug-independent ulcers ($p<0.001$). This study
monstrates the association between the severity
hepatic failure and the pathogenesis of
morrhage and the role of stress as a cause of
eeding ulcers in the presence of severe
patic disease.

3484 SOME INDICES OF NONSPECIFIC IMMUNITY IN LIVER CIRRHOSIS AND THEIR CLINICAL ASSESSMENT. (Rus.) Afanasiev, S. S.; Afanasieva, K. A.; Chirkin, Yu. D.; Ablaeva, T. D.; Podobedov, G. M. (Astrakhan' Medical Inst., Astrakhan', USSR). *Sov. Med.* (5):103-107; 1975.

3485 PROSPECTIVE STUDY OF QUANTITATIVE VARIATIONS IN THE PLASMA LEVELS OF ALPHA-FETOPROTEIN IN LIVER CIRRHOSIS. (Fre.) Delmont, J.; Schenowitz, G.; Masseyeff, R. (C.H.U. de Nice, avenue Reine-Victoria, F 06000 Nice, France). *Biol. Gastroenterol. (Paris)* 9:337-338; 1976.

3486 ASSESSMENT OF THE RISK OF THERAPEUTIC PORTACAVAL SHUNT IN CIRRHOSIS BY MULTIFACTORIAL ANALYSIS. (Fre.) Gauthier, A.; Cros, R. C.; Assadourian, R.; Di Costanzo, J. (Hopital Sainte-Marguerite, 270, boulevard Sainte-Marguerita, F 13274 Marseille Cedex 2, France). *Biol. Gastroenterol. (Paris)* 9:340; 1976.

3487 INITIAL EXPERIENCES IN THE TREATMENT OF CIRRHOTIC ASCITES BY CONTINUOUS ULTRAFILTRATION AND REINFUSION OF PROTEIN CONCENTRATE. (Ser.) Davcev, P.; Bidikov, V.; Vanovski, B. (Medical Faculty, Skopje, Yugoslavia). *Med. Pregl.* 28(7/8):285-290; 1975.

3488 DIGESTIVE TRACT HEMORRHAGE IN CIRRHOTIC PATIENTS AND STRESS. (Fre.) Franco, D.; Durandy, Y.; Deporte, A.; Bismuth, H. (Hopital Paul-Brousse, 14, avenue Paul-Vaillant-Couturier, F 94800 Villejuif, France). *Biol. Gastroenterol. (Paris)* 9:339; 1976.

3489 EFFECT OF AN ESTROGEN ON THE PLASMA CONCENTRATION OF RENIN SUBSTRATE IN CIRRHOSIS. (Fre.) Degos, F.; Descatoire, V.; Menard, J.; Benhamou, J. P. (INSERM U-24, Hopital Beaujon, F 92110 Clichy, France). *Biol. Gastroenterol. (Paris)* 9:337; 1976.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

90 COMPARATIVE EVALUATION OF TRI-IODIZED CONTRAST AGENTS FOR CHOLECYSTOCHOLANGIOGRAPHY.
us.) Popova, Z. P.; Ushakov. V. L.; Sviridov, N.
(Moscow Roentgenoradiological Inst., Dept. Roent-
nodiagnosis, Moscow, USSR). *Sov. Med.* (12):68-
; 1976.

The diagnostic value of cholecystocholangiography with various tri-iodized contrasting agents was studied in 704 patients. Oral cholecystography with cholevid, iopagnost, cystobil, osbil, solu-biloptin, and cholebrin was performed in 277 patients, and 477 patients underwent i.v. cholegraphy with bilignost, biligraphin, adipiodon, endocystobil, ultrabil, and biligran. Gallbladder visualization was observed in 57.9% of the patients undergoing i.v. cholegraphy and in 87% of the patients undergoing oral cholecystography; visualization of bile ducts was observed in 89.3% and 52% of the patients, resp. Side-effects (fever, nausea, and vomiting) were more common after i.v. cholegraphy (130/477) than after oral cholecystography (31/277).

3491 THE BIOCHEMICAL PREREQUISITES FOR PREVENTING PATHOGENIC LYSOLECITHIN ACTIVITY IN THE HUMAN GALLBLADDER. (Eng.)

Sjodahl, R.; Tagesson, C. (Dept. Surgery, Linkoping Univ., Linkoping, Sweden). *Scand. J. Gastroenterol.* 11(7):661-665; 1976

Experiments were carried out to study whether lysolecithin is affected by components from its implied target tissue, i.e., the gallbladder epithelium. When human gallbladder epithelium was incubated with lysolecithin (25-500 M/1.4 mg protein), lysolecithin was degraded, and stoichiometrically equivalent amounts of free fatty acids were formed. The maximum rate of degradation was obtained at pH 7.0 and at 200 µM lysolecithin. The rate of lysolecithin degradation increased with increased amounts of gallbladder epithelial cell components. Heating the epithelial components at 70 C for 10 min completely inhibited the degradation of lysolecithin. The results suggest the presence of a heat labile lysophospholipase (phospholipase B) activity in the human gallbladder epithelium. This activity may operate to protect gallbladder epithelium against potentially pathogenic lysolecithin activity. Its presence in the gallbladder epithelium indicates a local anti-inflammatory mechanism and supports the hypothesis that lysolecithin mediates cholecystitis.

3492 AMYLASE CREATININE CLEARANCE RATIO AFTER BILIARY SURGERY. (Eng.)

Donaldson, L. A.; McIntosh, W.; Joffe, S. N. (Stobhill Hosp., Glasgow, Scotland). *Gut* 18(1):16-18; 1977.

The value of the amylase:creatinine clearance ratio (ACCR) in the early recognition of postoperative acute pancreatitis was assessed in 25 patients undergoing elective cholecystectomy, and this ratio was compared with the serum amylase ratio. With the exception of one patient, the serum amylase level remained within normal limits postoperatively. The mean ACCR before operation was 2.6%, which significantly increased to a mean of 4.9% 24 hr after the operation ($p<0.005$). Five of seven patients in whom the ACCR exceeded 5.5% (mean 8.7%) had undergone common bile duct exploration during the cholecystectomy; this was in comparison with only 2 of the 17 patients with cholecystectomy in whom the ACCR was raised ($p<0.05$). By the ninth postoperative day, the ACCR had returned to normal in all patients. The mean serum amylase level significantly fell from a preoperative mean of 173 IU/1 to 140 IU/1 24 hr after operation ($p<0.01$). At the time of discharge, the mean serum amylase level was 214 IU/1. The ACCR appears to be a more sensitive index of pancreatic disruption secondary to biliary surgery than the serum amylase level.

3493 DIURNAL VARIATIONS IN THE pH OF PATHOLOGICAL GALLBLADDER BILE. (Eng.)

Sutor, D. J.; Wilkie, L. I. (Dept. Chemistry, Univ. Coll., London, England). *Gut* 17(12):971-974; 1976.

The pH of gallbladder and common duct bile from patients undergoing cholecystectomy was measured. The bile was collected and kept anaerobically at 37 C, and the pH was measured at 37 C, generally within 30-60 min after the bile was taken from the patient. Only data from patients having functioning or poorly functioning (but not nonfunctioning) gallbladders were included. The pH of common duct bile was always greater than that of the corresponding gallbladder bile, and this did not vary diurnally. The mean pH of gallbladder bile from patients undergoin operation at different times during the day showed a diurnal variation, the bile becoming more acidic with time. The mean pH at 830 was significantly higher than at 1030, 1400, and 1530 ($p<0.002$, <0.01, and <0.002, resp.). The mean pH at 1530 was significantly lower than at 1030 and at 1400 ($p<0.05$ and <0.04, resp.). The results also suggest a diurnal variation in the particular process responsible for the change in pH of gallbladder bile. Patients operated on in the afternoon fasted for several hou less than patients undergoing surgery in the mornin but bile for the two afternoon groups was significantly more acidic than that for the two morning groups, except for patients operated on at 1030 and 1400, when the mean pH values were comparable. However, the morning group probably slept or rested muc of the time because the fast was overnight, whereas the afternoon group was more physically active. Th acidification of bile is, therefore, apparently retarded during sleep, inactivity, or lying down.

3494 CHOLEDOCHAL CYSTS: A CLINICAL AND RADIOLOGICAL EVALUATION OF 21 CASES.

(Eng.) Bass, E. M.; Cremin, B. J. (Groote Schuur Hosp., Observatory, Cape Town, South Africa). *Pediatr. Radiol.* 5(2):81-85; 1976.

Experience with 21 cases of choledochal cyst is described, and 4 illustrative case reports are presented. Seventeen patients were female, and only three patients were over the age of 16 yr. Sixteen patients had concentric dilatation of the common bile duct; two patients had an eccentric diverticulum; two had multiple cystic dilatations of intrahepatic biliary radicles (Caroli's disease); and the remaining patient had dilatation of the distal end of the common bile duct or choledochocoele. Jaundice occurred in 17 patients, abdominal pain in 10, and a palpable abdominal mass in 11. The classical triad of all these features occurred in only five patients. Gallstones were found in two patients. All but two patients were treated surgically. Both unoperated cases had concentric ysts, and both patients, aged 5 and 6 months, esp., died. The first patient was found at utopsy to have had an atretic distal common ile duct, and the second patient died from evere gastroenteritis. Awareness of the roentenographic diagnostic possibilities of this conition, which are reviewed, will enable early iagnosis and surgical treatment.

495 CURRENT CONCEPTS OF THE PATHOGENESIS AND TREATMENT OF CHOLESTEROL GALLSTONES.

(Fre.) eaudoin, M.; Shaffer, E. A. (Laboratoire de Physioogie Digestive, Hopital Notre-Dame, 1560 Est, rue herbrooke, Montreal H2L 4K8, Canada). *Rev. Fr. Gasroenterol.* (116):29-42; 1976.

he various types of gallstones, factors predisposing owards formation of cholesterol gallstones (the most ommon type found in Western civilizations), and the onsurgical treatment of cholesterol bile calculi are eviewed. Research is in progress on several pharaceutical methods of decreasing the lithogenicity of ile and inducing calculi dissolution. Chenodeoxyholic acid appears to be the most promising agent at resent, although phenobarbital, heparin, and taurodiydrofusidate are also active in preventing or disolving cholesterol gallstones.

496 DIETARY CHOLESTEROL AFFECTS CHENODEOXYCHOLIC ACID ACTION ON BILIARY LIPIDS.

Eng.) Coyne, M. J.; Bonorris, G. G.; Chung, A.; ove, H.; Schoenfield, L. J. (Cedars-Sinai Medical enter, 8700 Beverly Boulevard, Los Angeles, CA 0048). *Gastroenterology* 72(5, Part 1):927-931; 977.

he effect of high and low dietary cholesterol on he chenodeoxycholic acid (CDC)-induced decrease of iliary saturation and activity of hepatic hydroxyethylglutaryl coenzyme A reductase (HMG-CoAR) was tudied. Seventy-two hamsters in six groups were ed one of three diets for 1 month: 0.8 mg of holesterol per g of food, 2.4 mg of cholesterol er g, or cholesterol-free. On each diet, hamsters eceived no CDC or CDC (30 mg/kg/day). The animals ere killed, biliary lipids were determined, and the ctivity of hepatic HMG-CoAR was assayed. CDC adinistration decreased the saturation index (SI, <0.01) in hamsters on the high cholesterol and stanard diets, but not on the cholesterol-free diet. he SI in CDC-treated hamsters on the high choleserol (0.78 ± 0.03) and cholesterol-free (0.68 ± .02) diets was greater ($p<0.02$) than in CDC-treated amsters on the standard diet (0.48 ± 0.03). CDC ecreased ($p<0.01$) HMG-CoA reductase activity on ach diet. In comparison to HMG-CoAR activity 190 ± 7.6 pmol/mg/min) in CDC-treated hamsters on he standard diet, the activity in CDC-treated hamters on the high cholesterol diet (176 ± 5.8 pmol/g/min) was decreased ($p<0.05$), whereas the activity n the cholesterol-free diet (495 ± 11.5 pmol/mg/min) as greater ($p<0.01$). It is concluded that: dietary holesterol is necessary for optimum CDC inhibition f HMG-CoAR, that high cholesterol and cholesterolree diets prevent maximum CDC decrease of the biliary saturation index, and that dietary cholesterol alterations may be one cause of the failure of CDC dissolution of gallstones.

3497 SPEED OF CHANGE IN BILIARY LIPIDS AND BILE ACIDS WITH CHENODEOXYCHOLIC ACID--IS INTERMITTENT THERAPY FEASIBLE?

(Eng.) Iser, J. H.; Murphy, G. M.; Dowling, R. H. (Guy's Hosp., London Bridge, SE1 England). *Gut* 18(1):7-15; 1977.

To see whether intermittent chenodeoxycholic acid (CDCA) therapy is a potential alternative to continuous treatment for gallstone dissolution, the speed of change in bile lipid composition was studied after starting and stopping CDCA therapy. The relationship between bile lipid composition and the proportions of the bile acids was also examined. Bile-rich duodenal fluid was collected twice in the first week and at approximately weekly intervals for 4-6 weeks, from six gallstone patients starting 13-15 mg CDCA/kg/day and from another group of six patients whose treatment was stopped after gallstone dissolution. After starting treatment, the mean biliary cholesterol saturation index decreased from 1.49 ± 0.17 to 0.92 ± 0.13 at 3 weeks and to 0.88 ± 0.10 at 4 weeks, by which time bile lipid composition had become relatively constant. In patients whose treatment was stopped, bile reverted to its supersaturated state within 1 week, changing from an on-treatment mean saturation index of 0.74 ± 0.10 to 1.15 ± 0.15 in 6-8 days after withdrawing CDCA. The proportion of conjugated CDCA in the biliary bile acids increased from 27.9 ± 2.5% to 60.5 ± 4.2% within 4 days and to 80.7 ± 6.2% by 4 weeks after starting CDCA. When treatment was stopped, the proportion of CDCA reverted to pretreatment levels by 2-3 weeks. The saturation index was significantly related ($p<0.001$) to the percent of conjugated CDCA present, such that when the proportion of CDCA exceeded 70%, bile was almost invariably unsaturated. Since the mean time taken for bile to become unsaturated was not shorter than the time taken for bile to revert to its supersaturated state, it seems that intermittent treatment would not be adequate to maintain an unsaturated bile and is, therefore, unlikely to be as effective as continuous treatment in dissolving gallstones.

3498 CHANGES IN BILE ACID METABOLISM DURING TREATMENT WITH CHENODEOXYCHOLIC ACID. STUDIES ON THE IMPORTANCE OF URSODEOXYCHOLIC ACID FOR GALLSTONE DISSOLUTION.

(Ger.) Fromm, H.; Erbler, H. C.; Eschler, A.; Schmidt, F. W. (Montefiore Hosp., Pittsburgh, PA 15213). *Klin. Wochenschr.* 54(23):1125-1131; 1976.

Significant changes in biliary composition of bile acid were established in nine patients with radiolucent gallstones under long-term chenodeoxycholic acid (CDC) therapy. The CDC concentration increased from 47.5 ± 4.21 to 79.2 ± 6.37 SEM%, ursodeoxycholic acid (UDC) increased from 2.7 ± 1.15 to 13.4 ± 6.47%, unsulfated lithocholic acid increased from 0.7 ± 0.22 to 2.7 ± 0.41%, and bile acid pool expanded by 130% (average). The highest increase in pool size was found in patients with the highest UDC concentration in the bile. Gallstone dissolution was observed in the five patients with the highest UDC concentration, indicating the cholelitholytic effect *in vivo* of UDC. The adequacy of the therapeutic CDC dose of 20 mg/kg/day was demonstrated by its 94% absorption (average) by patients.

3499 EFFECT OF VARYING DOSES OF CHENODEOXYCHOLIC ACID ON BILE LIPID AND BILIARY BILE ACID COMPOSITION IN GALLSTONE PATIENTS: A DOSE-RESPONSE STUDY.

(Eng.) Thistle, J. L.; Hofmann, A. F.; Yu, P. Y. S.; Ott, B. (Mayo Clinic, Rochester, MN 55901). *Am. J. Dig. Dis.* 22(1):1-6; 1977.

Dose-response information was obtained from 13 patients with radiolucent gallstones who received a formulation of chenodeoxycholic acid (chenic acid; 0, 250, 500, and 700 mg/day) with complete bioavailability for randomized 6-week periods. The proportion of chenic acid in biliary bile acids increased in direct relation to dose. Lithocholic acid also increased, but ursodeoxycholic acid showed no significant change. Bile saturation decreased with increasing dose, but response was variable and achieved significance only at 750 mg/day. Cholesterol saturation was negatively correlated with the proportion of chenic acid in biliary bile acids. When biliary bile acids contained greater than 70% chenic acid (and ursodeoxycholic acid), bile became unsaturated. The data suggest that a dose of at least 10-15 mg/kg may be necessary to obtain desaturation in many gallstone patients.

3500 TREATMENT OF PATIENTS WITH GALLSTONES WITH CHENODEOXYCHOLIC ACID.

(Ger.) Leuschner, U.; Reber, E.; Erb, W. (Zentrum der Inneren Medizin der Universitat, Theodor-Stern-Kai 7, 6000 Frankfurt/Main, W. Germany). *Dtsch. Med. Wochenschr.* 102(5): 156-160; 1977.

The results of the treatment of 24 patients with gallstones with chenodeoxycholic acid (CH) are reported. CH was given as 250 mg capsules 4 times daily. Six patients dropped out of the study for various reasons at the start of treatment. The remaining 19 patients were treated from less than 3 months to over 1 yr. Follow-up of 12 of 19 patients showed that 6 had complete stone dissolution, and 1 patient had almost complete stone dissolution. Stone size remained unchanged in five patients. Surgery was required in two patients with biliary duct concrements. One patient showed no change despite 17 months of treatment. Side-effects developing during CH therapy in all 24 patients included diarrhea (14 patients), epigastric pressure (6), colic (4), increase in transaminase levels (5), raised alkaline phosphatase (2), raised gamma-GT (2), and pruritus (1).

3501 THE INFLUENCE OF VAGAL-NERVE AND SERUM-LIPIDS ON THE DEVELOPMENT OF BILE-STONES.

(Eng.) Hartung, H.; Schaefer, H. (Dept. Surgery, Univ. Freiburg, Freiburg, W. Germany). *Chir. Gastroenterol.* 10(2):221-223; 1976.

Thirty women with cholelithiasis were examined to determine whether they had any impairment of vagus nerve function and/or a disturbance in serum lipid levels. There were no significant differences in mean preoperative serum lipid values between these patients and healthy women. After cholecystectomy, the mean arterial levels of total lipids, phosphatides, free fatty acids, triglycerides, and cholesterol esters were significantly lower than before the operation ($p<0.01$, 0.02, 0.05, 0.05, and 0.01, resp.); the levels of total lipids, phosphatides, cholesterol, and cholesterol esters were also significantly lower in the venous blood. The percentual fraction of phosphatides and triglycerides were lower by 3% and 5%, resp., in the patients with cholelithiasis than in healthy women. The total gastric acid secretion was lower in patients with gallstones than in healthy subjects. After insulin stimulation, the increase in acid concentration in the gallstone patients took place 15 min later than in healthy subjects. The acid concentration curve in the patients was not as steep as in the healthy subjects, and the concentration dropped 15 min earlier. These results imply that the vagus nerve function may be impaired in patients with cholelithiasis.

3502 PRIMARY COMMON DUCT STONES.

(Eng.) Saharia, P. C.; Zuidema, G.; Cameron, J. L. (Johns Hopkins Medical Inst., Baltimore, MD). *Ann. Surg* 185(5):598-604; 1977.

In an effort to identify patients with primary common duct stones, cases of patients undergoing common duct exploration over a 24-yr period were reviewed; the clinical presentation, operative findings, surgical treatment, and long-term follow-up results are reported. Of 758 patients, 30 were identified as having primary common duct stones. Criter for diagnosis included at least a 2-yr symptom-free interval following cholecystectomy; soft, light brown stones or sludge present in the common duct; and the absence of a long cystic duct remnant or a biliary stricture from the previous surgery. The average age of the 30 patients was 66 yr. The interval between cholecystectomy and the diagnosis o primary common duct stones average 12 yr. Acute cholangitis was a frequent mode of presentation (16 patients), and 21 patients presented with right upper quadrant pain. At the time of surgery, the bile duct was often dilated out of proportion to the serum bilirubin level. Ampullary stenosis was present in only one patient. Twenty-six of the 30 patients had only stone extraction and insertion of a T-tube for treatment of their primary common duct stones. Twenty-two of the 26 were followed for an average of 4 yr and 9 months with no evidence of recurrent stones in 82% (18/22). Four patients developed recurrent primary common duct stones 1, 5, 5 and 7 yr later. It is concluded that most patients with primary common duct stones do well after stone extraction alone.

503 BILIARY BACTERIA AND HEPATIC HISTOPATHOLOGIC CHANGES IN GALLSTONE DISEASE. (Eng.)
linn, W. R.; Olson, D. F.; Oyasu, R.; Beal, J. M.
Northwestern Univ. Medical Sch., Chicago, IL).
nn. Surg. 185(5):593-597; 1977.

he frequency and severity of liver damage in 126 pa-
ients with gallstone disease and the role of bac-
eria in the development of these changes were as-
essed. Needle biopsy of the liver demonstrated
cute inflammation of portal triads in 19 patients,
finding not present in 27 control patients. Acute
nflammation occurred more often in patients with
cute cholecystitis (5/8) and choledocholithiasis
6/6) than in chronic cholecystitis (16/56). Cul-
ures of the biliary tract or liver were positive
n 23 of 64 patients. The frequency of positive
ile cultures increased with the severity of the
iliary tract disease. Five of six positive liver
ultures were from patients with acute cholecystitis
r choledocholithiasis. The data suggest that im-
airment of bile flow is responsible for the acute
epatic inflammatory changes.

504 ULTRASOUND AND JAUNDICE. (Eng.) Vicary,
F. R.; Cusick, G.; Shirley, I. M.; Black-
ell, R. J. (Univ. Coll. Hosp., London, England).
ut 18(2):161-164; 1977.

ltrasound was used in 26 jaundiced patients to dif-
erentiate between extrahepatic biliary obstruction
nd other causes of jaundice. Eighteen patients
ere scanned with a conventional B-scanner, and
ight were scanned with a grey-scale machine. Sat-
sfactory scanning was not possible in two patients
or technical reasons. It was possible to differen-
iate correctly between extrahepatic obstruction and
ther causes in 23 of the remaining 24 patients.
xtrahepatic jaundice was diagnosed in 9 of 10 pa-
ients. Stones were diagnosed in five patients,
lthough they were correctly diagnosed as causing
bstruction in only three of the five. The use of
ltrasonic techniques in the jaundiced patient of-
ers a high degree of accuracy to the clinician and
ittle or no discomfort to the patient.

505 EXTRAHEPATIC BILIARY TRACT OBSTRUCTION SECONDARY TO A HEPATOMA-CONTAINING
LOOD CLOT IN THE COMMON BILE DUCT. (Eng.)
rand, S. N.; Brandt, L. J.; Sprayregan, S.;
renner, S.; Bernstein, L. H. (Montefiore Hosp., 111
. 210th St., Bronx, NY 10467). *Am. J. Dig. Dis.*
1(10):905-909; 1976.

The case of a 76-yr-old man with a hepatoma who
resented with obstructive jaundice secondary to
ntraductal obstruction by a blood clot contain-
ng tumor cells is described. The patient pre-
sented with anorexia, weight loss, jaundice,
ruritus, dark urine, and acholic stool. Se-
lective celiac arteriography showed a localized
area of neovascularity in the right lobe of the
liver. A ^{99m}Tc liver scan revealed two discrete
filling defects in the right lobe, one of which
corresponded to the area of neovascularity demonstrated by arteriography. Intraoperative cholangiography showed reflux into dilated right and left hepatic ducts. A 4-cm partially organized blood clot filled the common bile duct lumen. The head of the pancreas, stomach, and colon were normal, and there was no evidence of metastatic disease to the regional lymph nodes or the omentum. A cholecystectomy and a choledochoduodenostomy were performed. Malignant epithelial cells consistent with hepatoma were found within the blood clot. A subsequent prostate biopsy revealed infiltrating adenocarcinoma. The patient has remained clinically well on weekly 5-fluorouracil therapy, although the liver remains enlarged and the alkaline phosphatase level remains elevated at 184 IU. The angiographic finding of a hypervascular lesion with hemobilia is presumptive evidence for a hepatoma, as hemobilia has not been reported with metastatic disease to the liver.

3506 SPONTANEOUS PERFORATION OF THE EXTRAHEPATIC BILE DUCTS IN INFANCY. (Eng.)
Hartong, J. M. (William Beaumont Army Medical Center, El Paso, TX 79920) *Am. Surg.* 42(10):795-800; 1976

A case of spontaneous perforation of the bile duct occurring in a 4-week-old girl is presented, and the literature concerning this entity is briefly reviewed. The child was hospitalized with scleral icterus, dark urine, and white stools. An upper gastrointestinal series revealed displacement of the stomach by a mass in the upper right abdomen. Exploratory celiotomy revealed a large bile pseudocyst anterolateral to the liver, communicating with a smaller bile pseudocyst at the junction of the cystic duct with the common duct. The cystic duct was totally avulsed from the common duct. A cholecystectomy was performed, and the perforation in the common duct was closed. A literature review reveals that other infants with bile duct perforation have a similar history. Recovery is to be expected in all patients in whom the bile is sterile.

3507 CONTRIBUTION TO THE STUDY OF "PORCELAIN GALLBLADDER." (Ita.) Costantini, R.; Zanaboni, M. (Divisione Chirurgica, Ospedale Generale Provinciale "Galmarini," Tradate, Italy). *Minerva Med.* 66(80):4242-4247; 1975.

A very rare case of gallbladder calcification ("porcelain gallbladder;" "vicarious gallbladder") is reported in a 54-yr-old woman hospitalized with a diagnosis of ulcerated duodenitis. The radiography of the gastrointestinal tract followed by cholecystography showed intense calcification in the gallbladder, and was diagnosed as lithiasic cholecystopathy. The cholecystotomy revealed very thickened (2-3 mm) and hard gallbladder walls, which were clearly calcified and extremely resistant to scalpel penetration. The cavity contained five calculi covered by a thin calcareous shell. Only the neck of the gallbladder--also thickened--showed no calcification, but ended in a blocked fundus towards the completely occluded cystic duct. The histological examination showed almost complete modification of all structures. The gallbladder walls were formed by dense connective tissue, with collagenous fibers showing deposits of calcium salts. The mucosa was almost absent and was replaced by deposits of cholesterol. This is the case of "porcelain gallbladder" from a population of 2,000 cholecystectomies, and only about 60 cases were reported between 1797 and 1966. The pathogenesis of "porcelain gallbladder" depends on concurrent mechanical (occlusion of the cystic duct) and inflammatory factors, the slow evolution of which may lead to the deposition of calcium salts. The symptoms are those of chronic cholecystopathy, and cholecystectomy is the only possible treatment.

3508 SENILE COMMON BILE DUCT: RADIOLOGICAL STUDY. (Fre.) Djian, A.; Paraf, A.; Benoit, A.; Svirchevsky, I. (Service de Radiologie, C.H.U. de Bobigny 93000 Paris, France). *Sem. Hop. Paris* 52(35): 1917-1920; 1976.

An attempt was made to correlate the diameter of the common bile duct (CBD) with the age and disease of patients. A radiological study of 117 patients revealed no difference in the frequency and density of opacification or morphology of the CBD, regardless of age (less than 30 to 90 yr). Of the 117 patients, 15 had common bile duct disease, 12 had hepatic diseases, and 39 had other related diseases. In these 66 patients, the mean corrected diameter of the CBD of patients less than 30 yr of age was 2.7 ± 0.8 mm, whereas the eldest patients (89-90+ yr) had a diameter of 7.0 ± 1.5 mm. It is concluded that the real diameter of the CBD increases 1 mm/10 yr of age. Similarly, it was also shown that the diameter of the hepatic canal also increases with age.

3509 THE EFFECT OF CHOLESTYRAMINE ON THE DYE EXCRETION OF THE LIVER [Abstract]. (Eng.) Pieragnoli, E.; Gallerini, L. (Hosp. Greve, Greve, Italy). *Digestion* 14(5/6):540-541; 1976.

GENERAL

521 CLINICAL STUDY OF GASTROINTESTINAL COMPLICATIONS ASSOCIATED WITH CLINDAMYCIN
HERAPY. (Eng.) Swartzberg, J. E.; Maresca, R. M.;
emington, J. S. (Palo Alto Medical Res. Foundation,
60 Bryant St., Palo Alto, CA 94301). *J. Infect.
is.* 135(Suppl.):S99-S103; 1977.

he incidence of and factors associated with diar-
hea were evaluated in 1,000 patients receiving
lindamycin. Diarrhea occurred in 6.6% of the
atients. Diarrhea occurred nearly twice as often
n patients over 20 yr of age than in younger
atients ($p<0.01$). Diarrhea occurred in females
n 74.2% of the total cases. The incidence of
iarrhea was higher in patients who received the
rug p.o. (7.0%) than in those who received it
arenterally (2.2%, $p<0.05$). There was no corre-
ation between dose of drug or duration of therapy
nd diarrhea. Diarrhea began within 48 hr of the
tart of clindamycin therapy in 52.3% of the patients
nd within 5 days of therapy in 75.3%. Nineteen
atients developed diarrhea after they had stopped
eceiving the antibiotic. The duration of diarrhea
aried considerably, with a mean of 11.4 days
nd a range of 1-120 days. The benign nature of
he diarrhea in this patient population is note-
orthy.

522 GASTROINTESTINAL SIDE EFFECTS OF CLINDAMYCIN AND AMPICILLIN THERAPY. (Eng.)
usk, R. H.; Fekety, F. R., Jr.; Silva, J., Jr.;
odendorfer, T.; Devine, B. J.; Kawanishi, H.;
orff, L.; *et al.* (Univ. Michigan Medical Center,
nn Arbor, MI 48109). *J. Infect. Dis.* 135(Suppl.):
111-S119; 1977.

ospitalized patients who received clindamycin or
mpicillin were evaluated for gastrointestinal
ide-effects for up to 6 weeks after therapy was
iscontinued. Of 104 patients receiving clindamycin,
1 (29.8%) developed diarrhea, and 2 (1.9%) de-
eloped pseudomembranous colitis (PMC). Of 138
atients receiving ampicillin, 24 (17.3%) developed
iarrhea, and 1 (0.7%) developed PMC. Diarrhea
ersisted for 3 or more days in 13 (12.5%) patients
eceiving clindamycin and in 7 (5.1%) of those receiving ampicillin. The tendency to develop diarrhea was positively correlated with serious illness, abdominal or pelvic sepsis, and total dosage of clindamycin. Examination of stools from a patient with PMC that was associated with clindamycin therapy showed a decrease in the number of anaerobic bacteria over the numbers found in normal controls. Patients who did not develop diarrhea also had fewer anaerobic bacteria and coliform organisms. Lymphocytes from the patient with PMC were hyporeactive to phytohemagglutinin and hyperreactive to clindamycin. The results indicate that the symptoms of diarrhea are more frequent and more severe with clindamycin than with ampicillin.

3523 DIARRHEA ASSOCIATED WITH CLINDAMYCIN AND AMPICILLIN THERAPY: PRELIMINARY RESULTS OF A COOPERATIVE STUDY. (Eng.) Gurwith, M. J.; Rabin, H. R.; Love, K.; *et al.* (Health Sciences Center, 700 William Ave., Winnipeg, Manitoba R3E 0Z3, Canada). *J. Infect. Dis.* 135(Suppl.):S104-S110; 1977.

Patients treated with clindamycin were monitored for the development of diarrhea and colitis in a cooperative study at three hospitals. Ampicillin-treated patients were matched with clindamycin-treated patients. Diarrhea occurred in 62 (18%) of 343 clindamycin-treated patients, compared with 16 (5%) of 315 ampicillin-treated patients ($p<0.001$). The rate of diarrhea associated with clindamycin therapy ranged from 10% to 23% among the three hospitals, compared with 0 to 10% for ampicillin therapy. The only identified risk factor in the development of diarrhea was increased age; clindamycin-associated diarrhea occurred in 18 (46%) of 39 patients 60 yr old or older. No correlation was observed between the risk of diarrhea and the duration of treatment, total dosage of drug, route of administration, or type of underlying disease. Pseudomembranous colitis was diagnosed in 7 (2%) of 343 patients treated with clindamycin and in 1 (0.3%) of 315 patients treated with ampicillin. The data suggest that diarrhea occurs more frequently in patients treated with clindamycin than in those treated with ampicillin.

GENERAL

3524 LABORATORY CONFIRMATION OF AN OUTBREAK OF Clostridium perfringens FOOD POISONING. (Eng.) Schiemann, D. A. (Ontario Ministry Health, Public Health Lab., Box 9000 Terminal A, Toronto, Ontario M5W 1R5, Canada). *Health Lab. Sci.* 14(1): 35-38; 1977.

A food poisoning outbreak provided an opportunity to evaluate previously suggested criteria for *Clostridium perfringens* food poisoning. Eleven persons (44-73 yr old) ate the suspect meal and reported symptoms of gastroenteritis 13-13.5 hr later. The symptoms included abdominal cramps and diarrhea; one patient also reported vomiting, and two described general weakness. *C. perfringens* food poisoning was confirmed by the following criteria: the *C. perfringens* count in the suspect food, chicken pie, was at least 10^5/g; the median fecal *C. perfringens* spore count in convalescing patients exceeded 10^6/g; an identical serotype (PS63) was isolated from both the food and fecal specimens; and the *C. perfringens* isolates from eight patients were of the same serotype. The results confirm the usefulness of fecal spore counts and serotyping in implicating *C. perfringens* in food poisoning outbreaks.

3525 VARIATION IN ENTEROTOXIGENICITY OF Escherichia coli. (Eng.) Echeverria, P.; Louria, C. J.; Smith, A. L.; Smith, D. (Children's Hosp. Medical Center, 300 Longwood Ave., Boston, MA 02115). *J. Infect. Dis.* 135(2):195-200; 1977.

To examine the possibility that the variable severity of diarrheal disease due to enterotoxigenic *Escherichia coli* is due to quantitative differences in the activity of heat-labile enterotoxin, the amount of toxin secreted by 13 enteropathogenic strains of *E. coli* was quantitated. The toxin-dependent increase in adenosine 3':5'-cyclic phosphate (cyclic AMP) was measured in Chinese hamster ovary cells. The activity ranged from 150 pmol of cyclic AMP/ml/mg protein to 4,040 pmol/ml/mg. With three representative strains, there was good correlation ($r=0.999$; $p<0.05$) between the amounts of cyclic AMP accumulated intracellularly (4,040, 2,071, and 470 pmol of cyclic AMP/ml/mg protein, resp.) and the ability of the filtrate to distend the rabbit ileal loop, as measured by the amounts of toxin required to produce half-maximal distension (50% effective dose, which had values of 11.5, 27.5, and 38.5 mg, resp.). The observed strain-to-strain variation in toxin activity may explain the variation in severity of diarrheal disease caused by enterotoxigenic *E. coli*.

3526 KWASHIORKOR NOT ASSOCIATED WITH POVERTY. (Eng.) John, T. J.; Blazovich, J.; Lightner, E. S.; Siebr, O. F., Jr.; Corrigan, J. J.; Hansen, R. (Univ. Arizona Medical Center, Tucson, AZ 85724). *J. Pediatr.* 90(5):730-735; 1977.

The case reports of four infants with kwashiorkor not associated with poverty or infection are presented. The condition followed various dietary regimens deficient in protein of 5-weeks to 7-months duration. The symptoms included growth retardation, edema, muscle wasting, mental changes (apathy, irritability, and anorexia), and mild lymphocytosis. Hepatomegaly was present in one infant. Treatment included feeding of soy or cow's milk formulas and vitamin supplementatio Initially, recovery was associated with a rapid weigh loss (due to loss of edema) and decreased hemoglobin and hematocrit levels (2 patients), followed by subsequent weight gain and return to good health. Physicians should be aware of this "sugar-baby" form of kwashiorkor and its symptoms.

3527 ELEMENTAL DIET AS AN ALTERNATIVE TO INTRAVENOUS NUTRITION IN SEVERE GASTROINTESTINAL DISEASES. (Ger.) Goschke, H.; Buess, H.; Gyr, K.; Leutenegger, A.; Ott, S.; Stalder, G. A.; *et al.* (Kantonsspital, CH-4004 Basel, Switzerland). *Schweiz. Med. Wochenschr.* 107(2):43-49; 1977.

GENERAL

Parasitology

3557 FULMINANT NECROTIZING AMEBIC COLITIS IN CHILDREN. (Eng.) Balikian, J. P.; Bitar, J. G.; Rishani, K. K.; Kabakian, H. A. (American Univ. Medical Center, Beirut, Lebanon). *Am. J. Proctol.* 28(1):69-73; 1977.

The case of a 2.5-yr-old boy who died from necrotizing amebic colitis is presented. The patient presented with anorexia, occasional vomiting, and a 10-day history of diarrhea. A routine stool examination showed no ova or amebae. Proctoscopy showed necrotic rectal mucosa, and a biopsy disclosed ulcerations and *Entameba histolytic* trophozoites. The patient died before antiamebic therapy could be instituted. Roentgenograms of the abdomen showed evidence of peritonitis and a pericolic abscess; barium enema revealed a perforation in the cecum, with ulcerations throughout the colon. Amebiasis should be suspected in children presenting with diarrhea and/or acute abdomen; the diagnostic procedures should include stool examination, rectal scrapings or biopsy, and a plain abdominal film. Barium enema and surgery are contraindicated in the fulminant form of amebic colitis.

3558 GIARDIASIS IN COLORADO: AN EPIDEMIOLOGIC STUDY. (Eng.) Wright, R. A.; Spencer, H. C.; Brodsky, R. E.; Vernon, T. M. (Denver Disease Control Service, 605 Bannock St., Denver, CO 80204). *Am. J. Epidemiol.* 105(4):330-336; 1977.

A 1-yr retrospective laboratory survey of the epidemiology of giardiasis was carried out in Colorado. Six hundred ninety-one (3%) of 22,743 stool examinations for ova and parasites were positive for *Giardia lamblia,* a higher percentage than that reported from surveys outside of Colorado. The majority of infected residents surveyed had experienced an episode of chronic watery diarrhea (median duration 3.8 weeks) with bloating, flatulence, and weight loss (averaging 5.1 kg), and had responded to a course of metronidazole or quinacrine. A statewide telephone survey of 256 cases and matched controls identified: an increased incidence of giardiasis in persons between the ages of 16 and 45, $p<0.001$, with males and females equally affected; and a higher proportion of cases than controls who visited Colorado mountains (69% versus 47%), camped out overnight (38% versus 18%), and drank untreated mountain water (50% versus 17%), $p<0.001$. Also identified was a correlation between the seasonal distribution of cases and degree of fecal contamination of mountain streams. These results indicate that *G. lamblia* is endemic in Colorado and that drinking untreated mountain water is an important cause of endemic infection.

3559 INVASION OF SMALL INTESTINAL MUCOSA BY Giardia lamblia IN MAN. (Eng.) Saha, T. K.; Ghosh, T. K. (P-5, Lake Town, Block B, Calcutta 55, India). *Gastroenterology* 72(3):402-405; 1977.

Mucosal biopsies from the duodenum and jejunum of 31 patients with fecal *Giardia lamblia* cysts and/or trophozoites were studied histologically. Trophozoites were found in the lumen of all biopsy specimens. In 12 patients, all of whom had diarrhea and steatorrhea, trophozoites were also found within the mucosa. They were seen at different stages in different sections, from the stage of entry into the epithelium up to their migration into the lamina propria. In two cases, the route of entry of the parasite into the mucosa was detected. In the first instance, one trophozoite had entered the mucosa, leaving behind a track-like space through which a second parasite had introduced its tail. Among the 12 patients in whom the trophozoite had entered the mucosa, 5 had normal mucosal architecture. In the remaining patients, partial villous atrophy and inflammatory cellular infiltration was present. Goblet cells were increased in all seven cases, and basal nuclear polarity was lost in six. Among the 19 patients without mucosal invasion, 17 had mucosal damage; the other 2 had changes similar to those seen in the patients with mucosal invasion.

3560 STUDIES ON SCHISTOSOMAL RECTAL AND COLONIC POLYPOSIS. (Eng.) Smith, J. H.; Said, M. N.; Kelada, A. S. (Univ. Texas Medical Branch, Galveston, TX 77550). *Am. J. Trop. Med. Hyg.* 26(1): 80-84; 1977.

To determine the etiology of schistosomal polyposis, colonic and rectal specimens from 30 patients with this complication were studied histologically. Schistosome eggs were commonly found in the muscularis mucosa at the base of both colonic and rectal polyps. Polyps occurred at sites where the number of schistosome eggs was concentrated, regardless of which species was present (i.e., *S. haematobium* or *S. mansoni*. The muscularis mucosa was obliterated by evolving granulomatous lesions or by calcified eggs in dense fibrotic tissue. The egg burdens in areas of rectal and colonic polyposis were 7,796 ± 2,860 eggs/g tissue and 2,114 ± 742 eggs/g, resp., for *S. haematobium* and 8,675 ± 2,217 and 18,629 ± 3,362 eggs/g, resp., for *S. mansoni*; the corresponding values for the respective species in noninvolved areas of the colon were 1,860 ± 1,155 and 556 ± 348 eggs/g. The findings indicate that colonic and rectal schistosomal polyposis is due to concentrated oviposition, which results in perforation and scarring of the rectocolonic muscularis mucosa.

3561 CHRONIC HUMAN SCHISTOSOMIASIS MANSONI: PATHOLOGY OF THE DISSE'S SPACE. (Eng.) Grimaud, J. A.; Borojevic, R. (Institut Pasteur, 77, rue Pasteur, 60365 Lyon, Cedex 2, France). *Lab. Invest.* 36(3):268-273; 1977.

The pathology and ultrastructure of Disse's spaces were studied in 22 patients with chronic schistosomiasis. In the space of Disse, a fine fibrillar layer was found within the strata of a bilayered endothelium and under the innermost endothelial cells. It was irregular and sometimes discontinuous, resembling a basement membrane. The space was wider than normal, containing thick bundles of collagen and isolated dispersed collagen fibers. The irregular projections of the hepatocytes, together with cell debris and collagen, completely filled the Disse's space. Other abnormalities in the hepatic lobule included hepatic sinusoids with hypertrophy and stratification of the endothelium, basement membrane-like deposits, perisinusoidal fibrosis, diminution of hepatocellular microvilli, and hepatocellular clasmatosis into the sinusoidal circulation. This transformation of an open circulation to a partly closed one may decrease the blood hepatocyte exchanges in schistosomiasis.

GENERAL

Regional Enteritis

3576 SULPHASALAZINE IN ASYMPTOMATIC CROHN'S DISEASE: A MULTICENTRE TRIAL. (Eng.) Lennard-Jones, J. E.; Baron, J. H.; Bennett, P. N.; Swarbrick, E. T.; Coghill, N. F.; *et al.* (St. Mark's Hosp., City Rd., London EC1V 2PS, England). *Gut* 18(1):69-72; 1977.

The possible value of sulphasalazine in the reduction of the relapse rate after resection or in asymptomatic patients with established disease was investigated. During a 6-yr period, 43 patients were included in a double-blind, controlled trial of sulphasalazine for 1 yr. There were two relapses in the control group and four in the sulphasalazine group. Five patients developed complications of their disease, one of whom died. Two patients in the control group and eight in the sulphasalazine group stopped treatment due to side-effects. No trend in favor of sulphasalazine over the control group was observed. The difficulties of trials such as this include the small number of patients, the varied nature of the disease, and the high incidence of complications.

3577 REGIONAL ILEITIS (CROHN'S DISEASE). II. ELECTROLYTE AND WATER MOVEMENT IN THE ILEUM DURING PERFUSION WITH BILE ACIDS. (Eng.) Krag, B.; Krag, E. (Gentofte Hosp., Univ. Copenhagen, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(5):487-490; 1976.

Electrolyte and water movement was studied by steady state perfusion in the ileum of 11 patients with regional ileitis. Six patients, who at the time of the investigation had diarrhea, showed a constant water and salt secretion during control perfusion; water secretion was 0.2 ml/min/25 cm ileum. The patients without diarrhea showed a mean absorption of 0.6 ml/min/25 cm ileum. When the ileum was perfused with a solution containing 0.25-2.50 mM glycochenodeoxycholic acid, electrolyte and water secretion was enhanced in the patients with diarrhea, and absorption was decreased in the patients without diarrhea. It is concluded that functional disturbances of salt and water absorption in the inflamed ileum may be important in the pathogenesis of diarrhea in patients with regional ileitis.

3578 UROLOGICAL COMPLICATIONS IN CHRONIC INFLAMMATORY DISEASES OF THE BOWEL. (Eng.) Sigel, A.; Botticher, R.; Wilhelm, E. (Urologische Universitatsklinik, Maximiliansplatz, D-852 Erlangen, W. Germany). *Eur. Urol.* 3(1):7-10; 1977.

Urological complications of inflammatory bowel disease (i.e., Crohn's disease, ulcerative colitis, and colon diverticulitis) are reviewed. Characteristically, there are two different processes by which urological complications occur: either penetration into the urinary bladder and formation of a colo- or ileovesicle fistula or unilateral inflammatory penetration into the retroperitoneum, which may constrict the ureter by fibrosis and produce obstructive damage to the kidney. Colovesical fistula is found more frequently in diverticulitis than in Crohn's disease, which penetrates predominantly from the ileum into the bladder. Right-sided ureteral stenosis is caused by Crohn's disease, while left-sided ureteral stenosis is caused by ulcerative colitis. Vesico-intestinal fistulae close without sequelae after resection of the diseased bowel segment, but the presence of retroperitoneal ureteral stenosis often necessitates nephrectomy, if bowel resection and ureterolysis is not carried out early enough. Nephrolithiasis, amyloidosis, and contracted bladder are other, less common, complications of chronic inflammatory bowel diseases.

3579 EFFECT OF CROHN'S DISEASE ON COLONIC DIVERTICULA. (Eng.) Berridge, F. R.; Dick, A. P. (Addenbrooke's Hosp., Cambridge, England). *Br. J. Radiol.* 49(587):926-929; 1976.

To study the effect of Crohn's disease on colonic diverticula, the cases of 15 patients in whom diverticular disease and Crohn's disease affected the same colonic segment were studied; the case reports of two such patients are presented. Thirteen patients who had more than one barium enema examination were divided into four groups: no change in diverticula when Crohn's disease spread to that part of bowel (2), diminished number of diverticula (6), complete disappearance of diverticula when the affected bowel became involved with Crohn's disease (3), and appearance of diverticula in an area of bowel previously affected by Crohn's disease (2). The disappearance of diverticula with the development of Crohn's disease and their reappearance in remission is probably related to the tone of the bowel wall, which, in turn, is affected by the amount of induration, edema, and/or fibrosis present.

3580 LYMPHOCYTE SUBPOPULATIONS IN CROHN'S DISEASE AND CHRONIC ULCERATIVE COLITIS. (Eng.) Sorensen, S. F.; Hof, L. (Rigshospitalet, Tagensvej 18, DK-2200 Copenhagen N, Denmark). *Acta Pathol. Microbiol. Scand.* [*C*] 85(1):41-48; 1977.

Lymphocyte subpopulations were studied in 16 patients with Crohn's disease and 16 patients with ulcerative colitis. None of these patients was on corticosteroids or cytostatics, but 25 received salicylazosulphapyridine. Circulating lymphocytes were significantly reduced in patients with Crohn's disease ($p<0.05$), with all subpopulations being equally involved. This nonselective decrease may be caused by actual cell loss into the affected gut lumen. Patients with ulcerative colitis had normal total lymphocyte counts. While both the B- and T-lymphocyte counts were unchanged in ulcerative colitis, the number of lymphocytes carrying neither sheep RBC receptors nor surface immunoglobulins was twice the control values ($p<0.01$). These may possibly be the same cells that have been shown to specifically lyse colonic epithelial cells *in vitro*. Although treatment with salicylazosulphapyridine *per se* does not seem to influence T-lymphocyte counts, colitis patients receiving this drug had distinctly higher counts than untreated patients.

3581 PRESENT TREATMENT OF CROHN'S DISEASE. (Fre.) Girodet, J.; Rougier, P.; Mignon, M.; Bonfils, S. (Hopital Bichat, 170, boulevard Ney, 75018 Paris, France). *Rev. Prat.* 26(59):4257-4263; 1976.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism a Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal trac Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

3584 HISTOCHEMISTRY OF MICROVASCULAR SMOOTH MUSCLE IN THE GASTROINTESTINAL TRACT. (Eng.) Granger, D. N.; Cook, B. H.; Granger, H. J.; Taylor, A. E. (Univ. Mississippi Medical Center, Jackson, MS 39216). *Microvasc. Res.* 12(2):157-167; 1976.

Metabolic heterogeneity of vascular smooth muscle in the submucosa of stomach, ileum, and colon was demonstrated by histochemical localization of enzymes representing major metabolic pathways. Biopsies of stomach, terminal ileum, and colon from 10 dogs were stained using standard histochemical techniques. Colon and stomach microvessels showed similar patterns of metabolic activity, including a potential for β-oxidation of fats (β-hydroxybutyrate dehydrogenase), a moderate level of anaerobic glycolysis (lactate dehydrogenase), and ATP production (isocitrate dehydrogenase, NAD diaphorase, and cytochrome oxidase). The colon, however, exhibited very high hexose monophosphate shunt activity, while this pathway was absent in stomach microvasculature. Neither of these tissues stored glycogen or neutral fat, yet, unlike the stomach, the colon did store free fatty acids. Ileal microvessels stored high levels of free fatty acids and glycogen and a small amount of neutral fat. The ileum showed a greater potential for anaerobic glycolysis, also exhibiting a potential for β-oxidation of fats and ATP production similar to that of stomach and colon vessels. Hexose monophosphate shunt activity was high in ileal vessels, and nonspecific esterase activity was moderate. Vessels in all three tissues were rich in myosin ATPase indicating availability for muscle contraction.

3585 ANALYSIS OF THE EFFECTS OF FOOD AND OF DIGESTIVE SECRETIONS ON THE SMALL INTESTINE OF THE RAT. I. MUCOSAL MORPHOLOGY AND EPITHELIAL REPLACEMENT. (Eng.) Clarke, R. M.; Ecknauer, R.; Feyerabend, G. (Faculty Medicine, Univ. Newcastle, Newcastle, 2308 N.S.W., Australia). *Gut* 17(11):895-899; 1976.

To separate the influence of bile and pancreatic secretions from the influence of food on mucosal morphology and epithelial replacement, a modified Roux-en-Y repositioning of rat small intestine was performed. The proximal segment (A) received only pancreatic and bile secretions; the second portion (B) received food and gastric juices directly from the stomach, and the distal segment (C) drained both segments A and B. Male (21) CHBB rats were used: seven were operated as described, seven were sham operated, and seven went unoperated. Five weeks after surgery, vincristine was injected, i.p., and the intestines removed. Cell production was assessed as well as villus height, crypt depth, and the crypt villus ratio in each of the three groups. Vincristine metaphase counts were higher ($p<0.001$) in segment B and segment C ($p<0.01$) of the operated animals than in the sham-operated or unoperated animals. In segment C, villus height was significantly greater ($p<0.05$) in operated than sham-operated rats. In segments A and B, the villus heights were not significantly different, but the proximo-distal gradient of villus height appeared to be abolished in the operated animals. The crypt depth was significantly increased in the operated rats for all specimens of the intestine taken distal to the terminal portion of A ($p<0.05$, $p<0.01$, $p<0.001$ for various specimens). The crypt/villus ratio was significantly higher in 3/4 sites examined in segment C of the operated rats. In segment B this ratio was significantly higher in operated than sham-operated rats at 2/3 sites, while there were no significant differences between operated and unoperated rats. Some of these changes in intestinal histology could be due to alterations in the output of gastrointestinal polypeptide hormones; however, it is more likely that these hormones cause systemic rather than local effects. A serious defect exists in this experimental model, because of the possibility that gastric secretions damaged the intestinal mucosa in segment B and caused changes that cannot necessarily be ascribed to food alone.

3586 MORPHOLOGY AND DISTRIBUTION OF THE "VASA RECTA" IN THE JEJUNOILEAL TRACT OF THE SMALL INTESTINE. (Ita.) Vitiello, F. S. (Cattedra di Anatomia Topografica, Univ. degli Studi, Rome, Italy). *Minerva Chir.* 30(13/14):813-816; 1975.

The course and distribution of the vasa recta in the jejunoileal tract of the small intestine was studied in 12 middle-aged subjects without vascular impairment of the abdominal aorta or anatomicopathological modifications of the gastroenteric apparatus. The investigation was made by x-ray after injection of contrast medium through a catheter in the mesenteric artery and by subsequent ligation of the jejunal and ileal arteries. It was found that the long and short vasa recta make up the terminal circulation of the small intestine. The long vasa recta are more numerous than the short, and their density and length decreases progressively in craniocaudal direction. The long vasa recta always originate from parallel arterial arcades, while the short may also originate from accessory arcades formed by anastomoses between the long vasa recta. Ramifications of the short vasa recta penetrate the intestinal wall. The vasa recta constitute an ideal vasculature for the entire intestinal wall as their anastomoses allow sufficient supplementary circulation in case of vascular resection during surgery or as a result of traumatic lesions.

3587 THE NORMAL RADIOLOGICAL ANATOMY OF THE HEMORRHOIDAL VASCULAR NETWORK. PRELIMINARY NOTE ON THE BASIS OF A STUDY OF 15 CASES. (Fre.) Bernard, A.; Parnaud, E.; Guntz, M.; Chome, J. (Hopital des Diaconesse 16, rue du Sergent Bauchaut F 75012 Paris, France). *Ann. Radiol.* 20(5):483-489; 1977.

The hemorrhoidal vascular network was studied in 15 patients by angiography (abdominopelvic angiography and selective inferior mesenteric arteriography), microscopy, anatomy, and radiography. Autopsy specimens were obtained from six patients and 30 samples taken during hemorrhoidectomies were studied histologically. In some instances, tissue samples were taken during removal of a rectal tumor. Several types of arterial vascularization were found. The principal arterial pathways followed the anterior and posterior right and left lateral walls of the anal canal. The superior hemorrhoidal artery seemed to be the principal rectal artery and was mostly found on the external surface of the rectum before perforating the rectal tunica 7-10 cm from the anus. The secondary branches perforated the rectal wall and disseminated into the submucosa. Abundant anastomoses were found between the branches of the superior hemorrhoidal vein, on the external surface of the rectal ampulla, and in the submucosa. Microscopy also revealed numerous nervous system elements, arteriovenous anastomosis and large vascular spaces. It is suggested that hemorrhoidal venous pools have a true regulatory role supplemental to that of the smooth muscle fibers of the anal submucosal musculature.

3588 DISTRIBUTION OF CARBONIC ANHYDRASE WITHIN THE GASTRIC MUCOSA. (Eng.) O'Brien, P.; Rosen, S.; Trencis-Buck, L.; Silen, W. (Harvard Medical Sch., Boston, MA). *Gastroenterology* 72(5): 870-874; 1977.

The distribution of carbonic anhydrase within the gastric mucosa was studied biochemically and histochemically. Bullfrog fundic mucosa was separated into fractions containing predominantly surface epithelial cells, mucous neck cells, and oxyntic cells, resp., and the carbonic anhydrase concentration of each fraction and of antral mucosa was measured. There were no significant differences between the enzyme concentrations of these fractions. The mean level was 12.4 U of activity/mg of protein. The cellular localization of carbonic anhydrase in the gastric fundic and antral mucosa of the bullfrog, rat, rabbit, and dog was studied using a specific histochemical technique. The enzyme was present in both parietal and nonparietal epithelium of all species and characterized a specific cell type in the dog antrum. The widespread distribution of high levels of carbonic anhydrase activity in both acid secreting and nonsecreting cells of the gastric mucosa suggests a possible role for the enzyme beyond one solely relating to acid secretion.

3589 A CLINICAL AND ANATOMICAL STUDY OF ANOMALOUS TERMINATIONS OF THE COMMON BILE DUCT INTO THE DUODENUM. (Eng.) Lindner, H. H.; Pena, V. A.; Ruggeri, R. A. (Sch. Medicine, Univ. California, San Francisco, CA). *Ann. Surg.* 184(5):626-632; 1976.

One thousand operative cholangiograms, selected out of 2,500 for clarity and interpretability from five San Francisco Bay Area hospitals, were studied to emphasize that a sizeable proportion of the sites of entrance of the bile duct into the duodenum are anomalous and therefore of major clinical significance. In 86.9% of the patients, the common bile duct entered the descending duodenum, but in 13.1% of the individuals, it entered either the junction between the descending and transverse duodena or the transverse duodenum. In another 5%, the duodenal eminence was well below the level of the crossing of the duodenum by the transverse colon. It is evident that the biliary ampulla and eminence are not always readily accessible through a duodenotomy incision, and presentation of the papilla through this incision might frequently entail time-consuming surgical manipulation and add to surgical morbidity. The creation of false biliary passages secondary to operative procedures on the distal common duct, though rare, could be avoided through awareness of the abnormal morphology. A cholangiogram prior to radical pancreatectomy should be carried out to demonstrate the site of entry of the common duct, greatly reducing the possibility of a postoperative pancreato-biliary fistula. In cases where the common duct is blocked by a stone or neoplasm and its distal portion cannot be filled with dye, the surgeon should proceed with caution so that a false passage is not made.

3590 HISTOENZYMOLOGICAL CHARACTERISTICS OF THE INTESTINAL MUCOUS MEMBRANE DURING THE EXPERIMENTAL FORMATION OF EXTERNAL INTESTINAL FISTULA. (Rus.) Topuria, Z. M.; Chkheidze, R. D. (Tbilisi State Medical Inst., Tbilisi, USSR). *Bull. Acad. Sci. Georgian S.S.R.* 84(1):213-215; 1976.

ABSORPTION - EXCRETION - TRANSPORT

3598 AN IN VIVO INVESTIGATION OF BARIUM MEALS. (Eng.) Simmonds, R. J.; James, A. M. (Dept. Chemistry, Bedford Coll., Univ. London, Regent's Park, London NW1 4NS, England). *Cytobios* 16(61):13-21; 1976.

An *in vivo* technique is described for the quantitation of barium sulfate retained in rat small intestine. In normally fed controls, the average weight of barium sulfate recovered from a 5-cm length of gut was 73.6 mg. Fasting and/or 24 hr of a sugar diet greatly lowered the amount of barium retained. In the pH range 4-8, the weight of radiopaque substance taken up remained constant. In stabilized preparations, the amount retained increased with the concentration of the suspension, up to a limiting value. When the gut was perfused with a mucolytic agent (*N*-acetylcysteine) before the radiopaque meal, the final weight of barium retained was as little as 20% of control values. Clinically, it would appear that a high level of stabilizing agent in the barium meal and a low-residue diet instead of a fast would improve the uniformity of coverage and the consistency of results.

3599 FATE OF ORALLY ADMINISTERED β-ACETYLDIGOXIN IN MAN. (Ger.) Flasch, H.; Schumpelick, V.; Koch, G. (Pharma-Forschung der Beiersdorf AG, Unnastrasse 48, 2000 Hamburg 20, W. Germany). *Arzneim. Forsch.* 27(3):656-659; 1977.

The fate of orally administered ^{3}H-β-acetyldigoxin (^{3}H-AC), 10 ml in 10% alcohol-water mixture, was investigated in 11 patients between the ages of 32 and 53 yr. Aspirates of gastric and duodenal contents were taken by stomach tube 5, 10, 25, 40, and 60 min after administration of drug in eight patients. Blood samples were taken intraoperatively from the portal vein after intraduodenal application of ^{3}H-AC in three patients who underwent cholecystectomy. Radioactivity in aspirates was determined in a Tricarb-Scintillation spectrometer and metabolites were extracted by chromatography. Analysis showed that after p.o. administration 90% of the drug remained unchanged in the stomach after 10 min and 43% after 60 min. Chromatography of gastric contents indicated that a small portion of ^{3}H-AC was changed to digoxin (5.5%), digoxigenin-bis-digitoxosid (0.9%), digoxigenin-mono-digitoxosid (1.3%), and digoxigen (2.3%). α-Acetyldigoxin was detected in duodenal contents. Digoxin (93%) was the main metabolite found in the portal vein. ^{3}H-AC passes rapidly through the stomach with a half-life of 10 min, and most of the glycoside is absorbed unchanged by passage through the intestinal wall. Digoxin is the active substance that reaches the heart.

3600 A STUDY OF THE ABSORPTION OF A BASIC DIET ADMINISTERED BY CONTINUOUS JEJUNAL PERFUSION: THE EFFECT OF THE RATE OF PERFUSION AND THE CONCENTRATION UPON THE ABSORPTION OF THE NUTRIENTS. (Fre.) Vidon, N.; Hecketsweiler, P.; Cortot, A.; Bernier, J. J. (INSERM U-54, Hopital Saint-Lazare, 107, rue du Faubourg-Saint-Denis, F 75010 Paris, France). *Gastroenterol. Clin. Biol.* 1(3):257-266; 1977.

The mechanisms of jejunal absorption of a basic diet (amino acids, glucose, and polyglucose chains) were studied in 30 healthy volunteers by the triple lumen tube perfusion method. The nutrient solution was perfused into the intestine at the level of the ligament of Treitz, and absorption was measured at 35-, 70-, and 105-cm lengths of the jejunum after 3-hr continuous perfusion. The concentration of the nutrients was 620 or 280 mOsm/kg and the flow rate was 1-4 ml/min. The quantity of carbohydrates absorbed increased with the length of the intestine traversed and the quantity perfused. Absorption decreased from the proximal to the distal segment or from the angle of Treitz to the ileum. Nitrogen was definitely absorbed in the first 35 cm below the point of infusion, and the efficiency of absorption increased in proportion to the amount perfused and in proximal areas of the intestine in comparison with distal segments. The osmolarity of the nutrients had little or no effect on the absorption. These experiments show that, at a flow rate of 3 ml/min, more than 1,170 kcal can be obtained in 24 hr in 35 cm of the jejunum and that the energy absorption decreases when the flow rate increases.

3601 EFFECTS OF BILE ACIDS, LECITHIN, AND MONOOLEIN ON AMINO ACID ABSORPTION FROM THE HUMAN DUODENUM.

(Eng.) DiMagno, E. P.; Malagelada, J.; Go, V. L. W. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Proc. Soc. Exp. Biol. Med.* 154(3):325-330; 1977.

Effect of lecithin, monoolein, and conjugated trihydroxy and dihydroxy bile acids on duodenal absorption of essential amino acids (EAA) was studied in healthy male volunteers. Groups of five subjects were given 100-min intraduodenal perfusions containing 13, 26, 52, and 78 mM of EAA mixture; the 78 mM mixture contained 10.65 mM threonine, 12.95 mM valine, 5.15 mM methionine, 11.25 mM isoleucine, 16.8 mM leucine, 6.7 mM phenylalanine, 13.45 mM lysine, and 1.05 mM tryptophan. Gastric and duodenal aspirates were analyzed for a nonabsorbable polyethylene glycol marker, and EAA absorption was calculated. Approximately 50% of the total EAA perfused was absorbed; methionine was absorbed most rapidly, isoleucine, leucine, and valine slightly more slowly, and lysine and threonine at the slowest rates. Groups of three to seven men were given intraduodenal 78 mM EAA perfusions in combination with 5 or 10 mM sodium taurocholate (TC), sodium chenodeoxycholate (TCDC), sodium taurodeoxycholate (TDC), monoolein (MO), TC + MO, or TC + lecithin. Significant ($p<0.01$) decreases in absorption of all EAA occurred with TC (50%) and TDC (65%). The 26% decrease in EAA absorption in the presence of TCDC was not significant. MO alone had no effect on EAA absorption, but added in conjunction with 10 mM TC MO restored EAA absorption to normal. Endogenous EAA secretion into the duodenum during saline (3 subjects) or TC (2 subjects) perfusion was minimal (about 3% of total EAA absorbed and <2% EAA perfused). The mechanism of bile acid inhibition of duodenal EAA absorption and its restoration by MO or lecithin was not elucidated by this study.

3602 ABSORPTION OF SHORT-CHAIN FATTY ACIDS FROM THE HUMAN ILEUM.

(Eng.) Schmitt, M. G., Jr.; Soergel, K. H.; Wood, C. M.; Steff, J. J. (2300 North Rockton Ave., Rockford, IL 61101). *Am. J. Dig. Dis.* 22(4):340-347; 1977.

The ileal absorption of the major short-chain fatty acids (SCFA) was investigated in eight normal volunteers by the triple-lumen perfusion technique. Each test solution contained acetate, propionate, or *n*-butyrate at a concentration of 0-100 mM; sodium, potassium, and bicarbonate concentrations were kept constant, as were pH and osmolality. Absorption of each SCFA was rate-limited with an apparent K_m between 22 and 27 mM and a calculated V_{max} between 0.54 and 0.82 mmol/hr/cm. Water, sodium, and chloride transport were not affected by substantial rates of SCFA absorption. Significant stimulation of calculated bicarbonate secretion and a rise in intraluminal pH were consistently observed. The results are compatible with either of two mechanisms for SCFA absorption: an anion exchange between bicarbonate (or hydroxyl) and SCFA ions, or protonation of the SCFA anion at the mucosal surface followed by simple diffusion of nonionized SCFA into the absorbing cell.

3603 INTESTINAL LYMPH FLOW AND LYMPHATIC TRANSPORT OF PROTEIN DURING FAT ABSORPTION.

(Eng.) Turner, S. G.; Barrowman, J. A. (London Hosp. Medical Coll., London E1 2AD, England). *Q. J. Exp. Physiol.* 62(2):175-180; 1977.

A substantial amount of protein appears to enter intestinal lymph following a fat meal of long-chain triglycerides (LCT) or medium-chain triglycerides (MCT). A volume of 0.5 ml of either LCT (85% triolein, 10% tripalmitin, and small amounts of trilinolein and tristearin), MCT (81% octanoic, 16% decanoic, and small amounts of hexanoic and dodecanoic acids), or 0.9% NaCl (test meal) were washed into the cannulated duodena of male Wistar rats with 0.5 ml 0.9% NaCl. The meal was administered 18 hr following cannulation of the duodenum and the main small intestine lymphatic vessel. Lymph was collected from the intestinal lymphatics in 40-min periods, three times before and eight times after the test meal. No significant changes in lymph volume (1.4 ± 0.2 ml/hr) or protein levels (20.2 ± 1.7 mg/hr) occurred in all four controls. Lymph flow increased to peak of 5.0-5.1 ml/hr from initial value of 1.0-1.5 ml/hr at 40-80 min after LCT feeding in 2/2 rats. Protein transport increased to 91-94 mg/hr, or approximately 136 mg more than controls, for duration of experiment. Lymph turbidity increased in LCT-fed rats. Following MCT feeding, protein transport rose, peaking at 48.7 ± 3.6 mg/hr, with a total of 72.4 mg excess protein transported in 320 min. Increase in lymph flow peaked at 3.5 ± 0.3 ml/hr, and no turbidity was noted.

3604 EFFECT OF THE LEVEL OF DIETARY PROTEIN INTAKE ON FAT ABSORPTION IN CHILDREN.

(Eng.) MacLean, W. C., Jr.; De Romana, G. L.; Graham, G. G. (Johns Hopkins Univ., 615 North Wolfe St., Baltimore, MD 21205). *Pediatr. Res.* 11(6): 774-778; 1977.

The effect on fat absorption of feeding diets providing 0%, 6.4%, or 12.5% of energy as protein was assessed in nine children aged 4-18 months. Liquid diets were prepared by high speed blending of calcium caseinate, a soy-cotton seed oil blend (80:20), sucrose, water, vitamins, and a mineral

ixture and fed p.o. five times per day. Diets
aried in the amount of protein and were fed to
aintain constant the intakes of fat and carbohy-
rate. All children began by consuming the diet
roviding 6.4% of energy as protein for a period
f 6 days: 3 days of adaptation, 3 days of metabolic
ollection of urine and stool. Successive 3-day
ietary periods and metabolic collections followed
n one of two sequences: 12.5%, 0%, 6.4% energy
s protein in five children; 0%, 12.5%, 6.4% energy
s protein in four children. Mean fat excretion
uring the two 6.4% periods did not differ signifi-
antly. Fat excretion was significantly greater
uring the period when no protein was consumed
23.9 ± 7.7% of intake) than during either the
eriod in which protein provided 6.4% of energy
$p<0.01$) or during that in which protein provided
2.5% of energy (10.0 ± 2.6% of intake, $p<0.001$).
he difference between the 6.4% and 12.5% periods
as not significant. Fecal fat, expressed as a
ercentage of fecal dry weight, was significantly
reater during periods when the diet contained no
rotein than during periods in which protein provided
ither 6.4% ($p<0.05$) or 12.5% ($p<0.01$) of energy.
dditional studies were carried out in a similar
ashion in six children consuming diets in which
rotein provided 5%, 9.6%, and 15% of energy. Fat
xcretion did not vary significantly with protein
ntake. Dietary protein facilitates the digestion
nd/or absorption of fat.

605 INTESTINAL ABSORPTION OF PHOSPHATE: ACTION
OF PROTEIN SYNTHESIS INHIBITORS AND GLUCO-
ORTICOIDS IN THE RAT. (Eng.) Ferraro, C.; Ladi-
esky, M.; Cabrejas, M.; Montoreano, R.; Mautalen,
. (Hospital de Clinicas, Catedra de Biofisica, Fac-
ltad de Medicina UNBA y Centro de Medicina Nuclear,
omision Nacional de Energia Atomica, Argentina).
. *Nutr.* 106(12):1752-1756; 1976.

he effect of actinomycin D, cycloheximide, and glu-
ocorticoids on the intestinal absorption of phos-
hate was studied in Wistar rats. The effective
ntestinal absorption of ^{32}P and ^{47}Ca was determined
imultaneously *in vivo* using a whole body counter.
ctinomycin D (1 μg/g, i.p., 13 and 6 hr before the
est) and cycloheximide (3 μg/g, i.p., 2 hr before
tudy) caused a significant diminution of the in-
estinal phosphate absorption (39.0 ± 3.4% of dose
as absorbed with actinomycin versus 55.0 ± 2.1% in
ontrols, $p<0.005$; 30.4 ± 5.7% with cycloheximide
ersus 44.5 ± 1.9% in controls, $p<0.005$). Calcium
bsorption was not altered. Experiments with the
n situ ligated loop technique were performed to
liminate the possibility that the action of the
rotein synthesis inhibitors could be due to an
ltered intestinal motility effect. Phosphate ab-
orption was also significantly diminished under
his condition. On the other hand, the administra-
ion of hydrocortisone (50 μg/g/day, i.p., 5 days)
roduced a significant inhibition of phosphate and
alcium absorption in the rat *in vivo*. The results
ndicate that proteins and/or enzymes with a rapid
urn-over are involved in the mechanism of phosphate
ntestinal absorption, and confirm previous obser-
ations that phosphate and calcium are transported
cross the intestine by different mechanisms.

3606 EFFECT OF DIETARY LACTOSE ON THE ILEAL ABSORPTION OF SODIUM TAUROCHOLATE IN THE RAT. (Fre.) Riottot, M.; Sacquet, E.; Leprince, C.; Mejean, C. (Laboratoire des Animaux sans Germes du C.N.R.S., C.N.R.Z., 78350 Jouy-en-Josas, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 284(4):309-311; 1977.

Four male Fischer rats fed a diet containing lactose showed increases in the rats of absorption of sodium taurocholate at the level of the ileum and increases in the bile acid content of the small intestine. The lactose did not, however, increase daily fecal excretion of bile acids. The authors conclude that dietary lactose increases the intestinal pool of bile acids by increasing their absorption rate in the ileum and that this effect is not due to a modification of bile acid synthesis.

3607 Na^+ TRANSPORT IN JEJUNAL CRYPT CELLS. (Eng.) Gall, D. G.; Chapman, D.; Kelly, M.; Hamilton, J. R. (Hosp. Sick Children, 555 Univ. Ave., Toronto, Ontario, Canada M5G 1X8). *Gastroenterology* 72(3):452-456; 1977.

The effect of epithelial differentiation on ion transport was examined by comparing sodium efflux from two isolated populations of cells, one from jejunal villi and the other from jejunal crypts. (Na^+-K^+)-adenosine triphosphatase (ATPase) activity was also studied. The enterocytes were isolated from Wistar rat jejunum by a dilation-vibration technique. Thymidine kinase, sucrase, and alkaline phosphatase activities were measured as markers of specific cell populations. Cells from the crypt region demonstrated lower (Na^+-K^+)-ATPase activity (7.7 ± 1.3 nmol inorganic phosphate/min/mg protein) than did cells from the villus region (22.8 ± 3.8 nmol/min/mg, $p<0.005$). The total and passive (1 mM ouabain) Na^+ efflux rate constants were also significantly lower in the crypt cells, both in sugar-free medium (7.7 ± 0.4 and 3.6 ± 0.4/hr, resp.) and in 10 mM glucose medium (8.4 ± 0.7 and 3.5 ± 0.3/hr, resp.) than in the villus cells (10.1 ± 0.2 and 6.7 ± 0.2/hr in sugar-free medium, $p<0.001$; 14.2 ± 0.4 and 6.9 ± 0.3/hr in glucose medium, $p<0.001$). The lower efflux rate constants in glucose medium demonstrated the failure of Na^+ transport to respond to an actively transported nonelectrolyte in the crypt cell population. It appears that the mechanism for coupled Na^+ and nonelectrolyte transport develops as the enterocyte differentiates and migrates onto the villus.

3608 INFLUENCE OF HYDROSTATIC PRESSURE GRADIENTS ON NET TRANSFER OF SODIUM AND WATER ACROSS ISOLATED RAT COLONIC MUCOSA. (Eng.) Wanitschke, R.; Nell, G.; Rummel, W. (I. Medizinische Universitatsklinik, Langenbeckstrasse 1, D-6500 Mainz, W. Germany). *Naunyn-Schmiedebergs Arch. Pharmacol.* 297 (2):191-194; 1977.

The dependence of the net transfer of water and sodium on hydrostatic pressure gradients from the serosal to the mucosal side of the rat colon was investigated in everted sacs of the stripped mucosa of

Wistar rats. In the range of 3-20 cm H_2O, both the net sodium and the net water transfer were linearly dependent on hydrostatic pressure. The hydraulic permeability coefficient of the colonic epithelium was 1.1 ml/g/hr/cm H_2O. At a pressure gradient of 5.8 cm H_2O, the net movement of water from the mucosal to the serosal side ceased. Above this pressure, a net movement of water in the opposite direction occurred. The net sodium movement from the mucosal to the serosal side ceased at 11 cm H_2O. At pressures higher than 11 cm H_2O, a hypotonic fluid appeared at the mucosal side. The regression lines for the net sodium and water movement were not parallel but rather had significantly different slopes ($p<0.05$). Oxyphenisatin (10^{-5} M) increased the hydraulic permeability of the colonic epithelium. The fluid appearing on the mucosal side was isotonic. It is probable that the net flux of sodium and water from blood into the gut lumen induced by oxyphenisatin is driven by the hydrostatic pressure in the subepithelial region resulting from the capillary filtration pressure.

3609 EFFECT OF PRE-ADMINISTERED FATS AND FATTY ACIDS ON THE INTESTINAL ABSORPTION OF TRYPTOPHAN IN THE RAT. (Eng.) Inui, K.; Yamakita, H.; Hori, R. (Inst. Pharmaceutical Sciences, Hiroshima Univ. Sch. Medicine, Kasumi 1-2-3, Hiroshima, Japan). *Chem. Pharm. Bull. (Tokyo)* 24(12):3075-3080; 1976.

The absorption of L- and D-tryptophan by rat small intestine was investigated using *in situ* recirculation and *in vitro* everted sac techniques. When 1 ml of octanoic acid was administered intragastrically 3 hr previously, the absorption of L-tryptophan was greatly inhibited. Administration of trioctanoin, oleic acid, octyl alcohol, and methyl octanoate caused a moderate inhibition, but triolein and olive oil had no significant effect. In control rats, the absorption of L-tryptophan proceeded according to Michaelis-Menten kinetics. The administration of octanoic acid had little effect on the affinity of the transport mechanism for L-tryptophan, but it decreased maximal transport capacity. These results were confirmed *in vitro*. The absorption of D-tryptophan was concentration-dependent and only partially inhibited by octanoic acid. It appeared attributable to simple diffusion. Since octanoic acid increased the total amount of protein released into the perfusate, it is possible that its inhibitory effect may be due to loss of the structural and/or functional integrity of the intestinal membrane.

3610 HUMORAL REGULATION OF VITAMIN B_{12} ABSORPTION BY PREGNANT MOUSE SMALL INTESTINE. (Eng.) Brown, J.; Robertson, J.; Gallagher, N. (Royal Prince Alfred Hosp., Missenden Rd., Camperdown, 2050, Australia). *Gastroenterology* 72(5):881-885; 1977.

Pregnant Sydney White mice were fed a p.o. dose of 40 ng of $^{57}CoB_{12}$ to determine the mechanism responsible for the increased vitamin B_{12} absorption observed during pregnancy. In *in vivo* experiments, there was a progressive increase in B_{12} absorption in the third week of pregnancy. The absorptive mechanism resembled that in nonpregnant animals in that the mechanism was saturable, and presumably intrinsic factor (IF)-dependent, and that it was localized to the ileum. *In vitro* studies of IF-$^{57}CoB_{12}$ binding to ileal homogenates confirmed the requirement for IF. Studies in late pregnancy showed that IF-$^{57}CoB_{12}$ binding to ileal homogenates, expressed as nanograms of IF-$^{57}CoB_{12}$ bound/mg protein, was twice that of nonpregnant animals. When ileal homogenates were prepared from mice on days 20-21 of gestation, IF-$^{57}CoB_{12}$ binding fell to nonpregnant levels within 2-4 hr of hysterectomy. Hourly injections of serum from mice in late pregnancy, or from a woman at the 37th week of gestation, maintained IF-B_{12} binding at levels reached during pregnancy, whereas nonpregnant serum was ineffective. This fact indicates that the number of IF receptors is regulated by a humoral agent. The observation that human pregnant serum also influences B_{12} binding by mouse ileal homogenates may indicate that the human small intestine responds in a manner similar to that in the pregnant mouse.

3611 INHIBITION OF WATER ABSORPTION BY RICINOLEIC ACID. EVIDENCE AGAINST HORMONAL MEDIATION OF THE EFFECT. (Eng.) Gadacz, T. R.; Gaginella, T. S.; Phillips, S. F. (Mayo Clinic, Rochester, MN 55901). *Am. J. Dig. Dis.* 21(10):859-862; 1976.

The mechanism by which ricinoleic acid inhibits water and electrolyte absorption was investigated in three dogs, each with a jejunal and an ileal Thiry-Vella loop. The isolated segments were perfused with isotonic electrolyte solutions (control) for 90 min. One loop was then perfused with 5 mM ricinoleic acid for an additional 90 min, while the other loop was perfused with the control solution. Loops perfused with ricinoleic acid all showed reduced fluid absorption. Perfusion of one loop with ricinoleic acid produced no changes in fluid absorption from the loop perfused with the control solution. In other experiments, 4 Ivy dog U/kg/hr of cholecystokinin produced no change in water movement in loops perfused with control solution or ricinoleic acid. The results suggest that the effect of ricinoleic acid on intestinal water transport is not mediated through the release of a circulating humoral substance.

3612 ^{65}Zn-LABELED TISSUE ZINC FOR DETERMINATION OF ENDOGENOUS FECAL ZINC EXCRETION IN GROWING RATS. (Eng.) Weigand, E.; Kirchgessner, M. (Institut fur Tierernahrung der Technischen Universitat Munchen, D-8050 Freising-Weihenstephan, W. Germany). *Nutr. Metab.* 20(5):314-320; 1976.

Experiments were carried out to ascertain whether body tissues other than plasma provide suitable endogenous zinc sources to determine endogenous fecal zinc excretion and zinc absorbability by the radioisotope dilution technique. In 16 Sprague-Dawley rats receiving 12 µCi ^{65}Zn-ZnCl$_2$, i.m., the apparent digestibility of zinc (12.8 mg Zn/kg diet dry matter) averaged 72.4 ± 6.2% during a 6-day balance period starting 9 days postinjection.

Based on the specific radioactivity of zinc in plasma after 10 days, two-thirds of the fecal zinc were of endogenous origin, and the corresponding zinc absorbability averaged about 91%. Zinc absorbabilities computed on the basis of the specific radioactivity of zinc in the small intestine, pancreas, and/or kidneys after 15 days were closely comparable to the mean derived with plasma. Other tissue examined (RBC, liver, bone, and skeletal muscle) were found to be less suitable as reflections of the specific radioactivity of endogenous fecal zinc. The pancreas, small intestine, and kidneys therefore represent useful sources of zinc for the determination of the specific activity of endogenous fecal zinc.

3613 EFFECT OF FASTING ON BODY FLUIDS AND INTESTINAL DRUG ABSORPTION IN RATS. (Eng.) Kitazawa, S.; Komuro, T. (Kyoto Univ. Hosp., Shogoin Kawahara-cho, Sakyo-ku, Kyoto, 606, Japan). *Chem. Pharm. Bull.* 25(2):327-337; 1977.

3614 CHARACTERISTICS OF INTESTINAL ABSORPTION FOLLOWING PROLONGED TOTAL PARENTERAL NUTRITION. (Eng.) Bury, K. D.; Grayston, M.; Kanarens, J. (Wellesley Hosp., Toronto, Ontario, Canada). *Surg. Forum* 26:22-24; 1975.

3625 EFFECT OF CIMETIDINE ON THE HUMAN LOWER OESOPHAGEAL SPHINCTER. (Eng.)

Osborne, D. H.; Lennon, J.; Henderson, M.; Lidgard, G.; Creel, R.; Carter, D. C. (Edinburgh Univ., Edinburgh, Scotland). *Gut* 18(2):99-105; 1977.

Lower esophageal sphincter pressures were measured in healthy volunteers by a rapid pull-through technique during the i.v. infusion of cimetidine (100 mg/hr). No consistent or clinically important effects on sphincter pressure were observed. Serum gastrin concentrations during cimetidine infusion were measured by radioimmunoassay and showed no significant variation. In a further series of experiments, the response of the lower esophageal sphincter to the i.v. bolus injection of pentagastrin (0.5 μg/kg) was measured before and during cimetidine infusion. Cimetidine infusion had no significant effect on the sphincter response to pentagastrin.

3626 CRITICAL STUDY OF THE ELECTRICAL ACTIVITY OF THE SMALL INTESTINE IN THE DOG. (Fre.)

Perissat, J.; Saric, J.; Chemin, P.; Masson, B.; Paty, J.; Doutre, L. P. (311, boulevard du President-Wilson, 33200 Bordeaux, France). *J. Chir. (Paris)* 112(3):191-198; 1976.

Two sections of the small intestine of a sacrificed dog, the duodenojejunal angle and the ileum (proximal to the colon), were isolated and maintained by cross-circulation in the abdomen of a second dog. The electrical activity of small intestine segments was measured by enterography with electrodes placed in the intestinal serosa and on the skin of the dog's abdomen. Readings were taken during spontaneous activity of the small intestine, anoxia, endoluminal mechanical stimulation, or after i.a. or intraluminal injections of metoclopramide, metopimazine, or neostigmine. Readings from the bipolar serosal intestinal electrodes demonstrated basal electrical rhythm (BER) with a frequency of 14-16/min identical at different levels of the jejunal and ileal intestine. The frequency of BER increased (20-22/min) during anoxia or after an i.a. injection of neostigmine. Contractions registered on the graph as spikes whose number and amplitude depended on intensity. Digestive tract spasms occurred when these spikes were numerous. BER and spikes, corresponding to intestinal motor activity, were recorded in only one instance from abdominal electrodes.

3627 PATHOPHYSIOLOGY OF POSTOPERATIVE ILEUS. (Eng.)

Smith, J.; Kelly, K. A.; Weinshilboum, R. M. (Dept. Surgery, Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Arch. Surg.* 112(2):203-209; 1977.

The following hypothesis was investigated in eight female dogs: that the augmented release of norepinephrine by the sympathetic nerves in the wall of the gut in postoperative ileus inhibits the regularly occurring interdigestive motor complexes that propel contents through the gut during fasting, but the gastrointestinal pacemakers and the pattern of pacesetter potentials propagating aborally from them are not disturbed. The treatment of postoperative ileus using sympathetic blocking agents was also explored. Celiotomy, rubbing the small bowel, and exposing it to the air promptly inhibited the interdigestive myoelectric complex. Action potentials, and hence contractions, occur with gastrointestinal pacesetter potentials during fasting before the operations, but the potentials and contractions are abolished or greatly inhibited after the operations. The frequency of the gastric pacesetter potential is decreased slightly 3 hr after the operation, but the frequency of pacesetter potential in the small bowel was unchanged. All of the dogs except one tolerated the administration of phentolamine and propranolol well. A pronounced but transient increase of epinephrine and moderate but prolonged increase of norepinephrine occur in arterial plasma after the operation. The concentrations of phentolamine and propranolol used block both alpha and beta receptors in the cardiovascular system of dogs. The doses were large enough to result in the death of one dog. These data suggest that the sympathetic nervous system is involved in postoperative ileus, but other factors may also have a role.

3628 TELEMETRIC ESTIMATION OF THE DESCENDING COLON PRESSURE CHANGES ON DOGS BEFORE AND AFTER TOTAL AND SELECTIVE VAGOTOMY. (Eng.)

Garas, J.; Besbeas, S.; Vassilopoulos, D.; Pateras, H.; Ramandanis, G. (G. Papanicolaou Res. Center Oncology and Experimental Surgery, 171, Alexandra Ave., Athens 603, Greece). *Eur. Surg. Res.* 8(5):411-418; 1976.

Telemetric estimations of descending colon pressure changes in mongrel dogs of both sexes were performed both before and 6 weeks after either total or selective vagotomy in combination with Finney's pyloroplasty. Preoperative basal pressure changes in the descending colon of dogs undergoing total vagotomy plus Finney's pyloroplasty varied from 25 to 35 cm water, with the mean pressure being 29.3 cm water; postoperative basal pressure changes varied from 3 to 10 cm water, with the mean basal pressure being 6.3 cm water at 6 weeks after surgery. The 78.7% decrease in colonic basal pressure after total vagotomy was statistically significant ($p<0.005$). The mean amplitude of the colonic pressure waves dropped from a preoperative value of 21.1 cm water to 2.1 cm water after total vagotomy. The activity of the descending colon was reduced from a preoperative value of 48.1% to a postoperative value of 3.2%. The colonic motility index was also reduced from a preoperative value of 1014.9 to a postoperative value of 6.7. In dogs undergoing selective vagotomy, there were no statistically significant changes in the preoperative and postoperative values of the mean basal colonic pressure (29.5 versus 29.8 cm water), the amplitude of the colonic pressure waves (18.6 versus 17.2 cm water), the activity of the descending colon (45.7 versus 46.2%), and the colonic motility index (850.02 versus 794.64). These results might be applicable to humans since colonic innervation and physiology in dogs is essentially similar to that in humans.

3629 THE VOLUMETRIC MEASUREMENT OF GASTRIC EMPTYING AND GASTRIC SECRETION BY A RADIOISOTOPE METHOD. (Eng.) Hinder, R. A.; Horn, B. K. P.; Bremner, C. G. (Univ. Witwatersrand, Medical Sch., Essenlen St., Johannesburg 2001, South Africa). *Am. J. Dig. Dis.* 21(11):940-945; 1976.

A refinement to a previously reported method for calculating gastric emptying is presented, which allows for the dilution of gastric juice by gastric secretion, duodenal reflux, and swallowed saliva. Radioiodinated human serum albumin ($[^{125}I]$RIHSA) and the Volemetron were used to measure gastric emptying in seven adult mongrel dogs trained to accept an orogastric tube and mouth gag without agitation; one test per day per dog was performed using meals of 20 ml/kg body weight plus 12 ml additional volume of reconstituted milk. The data obtained were subjected to regression analysis, and a mathematical model for treating the data is presented. Correlation analysis of experimental points to lines of regression for gastric outflow was performed for both linear and logarithmic plotting of the volumes. The correlation coefficients were significantly different ($p<0.05$) for these two plots; the classical exponential pattern of emptying the volume of the original meal was not demonstrated; rather, emptying of the entire gastric contents was found to be linear with respect to time.

3630 LOCALIZATION OF RECEPTORS INHIBITING GASTRIC EMPTYING IN THE GUT. (Eng.) Cooke, A. R. (Univ. Kansas Medical Center, Rainbow Blvd. and 39th St., Kansas City, KS 66103). *Gastroenterology* 72(5):875-880; 1977.

Experiments were carried out to localize receptors for the inhibition of gastric emptying responsive to acid, osmotic agents, a fatty acid, and tryptophan in the first part and second to fourth parts of the duodenum, the whole duodenum, and proximal jejunum. Five dogs were prepared, each with three fistulas; one fistula was placed in the stomach, the next in the first part of the duodenum, 5 cm from the pylorus, and the third at the junction of the duodenum and the jejunum. By combinations of test meals and perfusions, either a part of or the whole of the duodenum or jejunum was tested with 550-850 mOsm solutions (glucose, glycine, mannitol, or NaCl) 100 mM HCl, 10 or 20 mM sodium oleate, and 40 mM tryptophan for their effect on gastric emptying. Phenol red was used as a nonabsorbable marker. Gastric emptying was not slowed by perfusion of the whole duodenum with the hypertonic solutions of glucose, glycine, mannitol, and NaCl, or with 10 or 20 mM sodium oleate. In contrast, significant slowing of gastric emptying occurred with jejunal perfusion of the hypertonic solutions and sodium oleate. Jejunal perfusion of 100 mM HCl slowed gastric emptying, but perfusion of the second to fourth parts of the duodenum did not. Tryptophan slowed gastric emptying when allowed to perfuse the first 5 cm of the duodenum, the second to fourth parts of the duodenum, and also the jejunum. The findings indicate that the jejunum has receptors for inhibition of gastric emptying responsive to tryptophan, acid, fat, and hypertonic solutions. In contrast, the duodenum has receptors responsive to tryptophan.

3631 OSMOLYTE AND TRYPTOPHAN RECEPTORS CONTROLLING GASTRIC EMPTYING IN THE DOG. (Eng.) Stephens, J. R.; Woolson, R. F.; Cooke, A. R. (Dept. Medicine, Univ. Iowa, Iowa City, IA 52240). *Am. J. Physiol.* 231(3):848-853; 1976.

To further define the small intestine receptors responsive to osmolytes and tryptophan, the effects on gastric emptying in dogs of three monosaccharides, three disaccharides, two dipeptides, combinations of tryptophan with two hexoses, one hexitol, and two amino acids was studied. Gastric fistulas were created in six dogs in the most dependent part of the stomach with Thomas cannulas. Studies were begun 3 weeks postoperatively and continued for 7 months. All studies were performed without anesthesia, and all dogs remained healthy. Both the disaccharides and the dipeptides were almost twice as potent per mole as their constituent monosaccharides or amino acids in their respective effects on gastric emptying, indicating that hydrolysis had occurred before the dipeptides or disaccharides had reached the osmoreceptor. This phenomenon indicates that the osmoreceptor is deep to the brush border dipeptidases and disaccharidases. The effect of tryptophan on gastric emptying was inhibited by 50 mM methionine ($p<0.05$). Methionine had no effect on a stimulant of the osmoreceptor system. Lysine, unlike methionine, does not share the neutral amino acid pathway with tryptophan and did not alter the inhibitory effect of tryptophan on gastric emptying. This indicated that tryptophan must be transported into the intestinal cell to produce its effect. The hexoses (100 mM) and mannitol (100 mM) also inhibited the tryptophan effect ($p<0.05$) probably by competition for transport into the cell, whereas nonabsorbed hexitol or mannitol were without effect. These studies point to the existence of a tryptophan receptor different from the osmoreceptor.

3632 COMPARATIVE EFFECTS OF CERULEIN AND CHOLECYSTOKININ-PANCREOZYMIN ON ELECTRIC AND MANOMETRIC ACTIVITY OF HUMAN STOMACH. (Fre.) Bortolotti, M.; Labo, G. (IIa Clinica medica generale e Terapia medica, Via Massarenti 9, I 40138 Bologna, Italy). *Rev. Fr. Gastroenterol.* (122):5-22; 1976.

The effects of cerulein (Ce) and cholecystokinin-pancreozymin (CP) on the electric and manometric activity of the gastric antrum were compared in 23 subjects. Electric activity was registered by an electrode at the end of a stomach tube and a plate on the abdominal skin. A rubber balloon connected to a manometer via a small catheter was used to measure mechanical activity. Both parameters were transduced to an amplifier on an electromyograph. Measurements were taken 20-30 min after the stomach tube had been introduced for about 65 min, during which time a 0.15 mM saline solution was given i.v. (base period), followed by the i.v. injection of Ce (0.5-12.5 mg/kg) or CP (1-8 U/kg). The delayed effects of the agents were then registered for 20 min, after which time saline was again given. Ce and CP caused a statistically significant reduction in the frequency of the basic electrical rhythm and a decrease or disappearance of spikes and manometric waves. The onset and duration of action of Ce and CP were dose-dependent. After end of treatment, the increase in spike bursts and manometric activity was still above baseline values. On a weight and a molar basis, Ce was more potent than CP.

3633 PHARMACOLOGICAL ANALYSIS OF THE EFFECTS OF METOCLOPRAMIDE ON THE GUINEA PIG ISOLATED STOMACH. (Eng.) Hay, A. M. (Royal Postgraduate Medical Sch., DuCane Rd., London W12 OHS, England). *Gastroenterology* 72(5):864-869; 1977.

A pharmacological analysis was made of the effects of metoclopramide on the contractile activity of isolated longitudinal muscle strips prepared from the guinea pig stomach. Metoclopramide (5×10^{-6} g/ml) produced up to threefold increases in the amplitude of the spontaneous contractions exhibited by such a preparation. This phenomenon was antagonized by hyoscine (1×10^{-7} g/ml) but not by tetrodotoxin (1×10^{-7} g/ml) or by hexamethonium (5×10^{-5} g/ml). The contractile response to transmural stimulation was also enhanced by metoclopramide, as was the response to extrinsic acetylcholine. Neural inhibitory systems were not affected by metoclopramide. The apparent sensitization to extrinsic acetylcholine was, however, prevented by tetrodotoxin and hexamethonium, implying that this effect depends upon ganglionic stimulation by acetylcholine. These results suggest that metoclopramide may act by increasing the amount of acetylcholine released at the postganglionic cholinergic nerve ending.

3634 THE INFLUENCE OF TEMPERATURE OF INGESTED FLUID ON STOMACH EMPTYING TIME. (Eng.) Ritschel, W. A.; Erni, W. (Univ. Cincinnati Medical Center, 401 Health Professions Building, Cincinnati, OH 45267). *Int. J. Clin. Pharmacol. Biopharm.* 15(4):172-175; 1977.

The influence of the temperature of ingested water on the stomach emptying time of solid material was studied in healthy volunteers using a telemetric pH measurement device. The time of discharge of the indigestible capsule from the stomach into the duodenum was significantly faster when administered with 250 ml of water at 5 C (15.91 ± 10.04 min) than it was with water at 20-25 C (48.18 ± 28.97 min) or at 45 C (71.42 ± 37.08 min). These observations suggest that enteric-coated preparations and drugs that are inactivated by gastric fluid or that irritate gastric mucosa should be administered only with ice water (4-6 C). Stomach washings with charcoal to remove a poison should be performed with warm water (45 C).

3635 VAGAL GASTRIC RELAXATION IN THE DOG. (Eng.) Jahnberg, T.; Abrahamsson, H.; Jansson, G.; Martinson, J. (Sahlgren's Hosp., 413 45 Goteborg, Sweden). *Scand. J. Gastroenterol.* 12(2):221-224; 1977.

Vagal nervous control of gastric reservoir function was studied in anesthetized dogs. The administration of atropine (1.0 mg/kg) was followed by a decrease in gastric tone. Esophageal distension with a plastic balloon was followed within seconds by marked gastric relaxation. This response was still present after atropine (0.5-1.0 mg/kg) or after guanethidine (1.0 mg/kg) administration. Vagotomy increased gastric tone and abolished the gastric relaxation that normally followed esophageal distension. Efferent electrical stimulation of one peripheral vagal nerve end (voltage 5-15 V, duration 5-10 msec, frequency 5-10 sec) was accompanied by a marked gastric contraction, which was not followed by relaxation after removal of the stimulus. Atropine administration reduced or abolished this response.

3636 EFFECT OF VAGOTOMY ON THE RESPONSE OF GASTRIC MYOELECTRICAL ACTIVITY TO GLUCAGON AND FOOD. (Eng.) Stoddard, C. J.; Duthie, H. L. (Univ. Surgical Unit, Royal Infirmary, Sheffield, England). *Scand. J. Gastroenterol.* 11(42):77-83; 1976.

The effect of vagotomy on gastric myoelectrical activity was studied in 13 patients and 4 dogs. I.v. injection of glucagon (5 and 10 µg/kg) in three patients with intact vagi resulted in periods of increased frequency of gastric slow waves as well as periods of inhibition. These results persisted in seven patients after selective vagotomy, but were abolished in three patients with truncal vagotomy. Myoelectrical activity of the stomach and duodenum was measured in dogs after a meal of 450 g of meat. Coordination of spike activity superimposed on the slow waves decreased significantly after truncal vagotomy, but not after highly selective vagotomy. These results confirm that changes in myoelectrical activity are related to the extent of vagal denervation.

3637 ACTION OF CHOLECYSTOKININ AND CAERULEIN ON RABBIT SPHINCTER OF ODDI. (Eng.) Sarles, J. C.; Bidard, J. M.; Devaux, M. A.; Echinard, C.; Castagnini, A. (Centre Hospitalier, Avenue du Petit-Canedel, F-13667 Aubagne, France). *Digestion* 14(5/6):415-423; 1976.

To assess the effects of cholecystokinin (CCK) and cerulein on the rabbit sphincter of Oddi, electromyographic, manometric, and direct flow measurements were made after administration of varying doses of the hormones. Electrical activity, which can be defined as the number of spikes per burst, did not change significantly at doses of CCK from 1/16 to 1/4 IDU/kg, i.v. One-half to 8 IDU/kg led to a marked increase in sphincter activity (proportional to the logarithm of the dose) with a maximum near the first minute and a return to the basal level by the tenth minute ($p<0.05$). To determine whether the effect of CCK was due to impurities, cerulein was used in some rabbits. The sphincter response obtained with cerulein at doses between 2 and 10^{-9} g/kg was identical to the CCK-induced response. The biliary pressure-dose response to CCK paralleled the electromyographic response to CCK at identical dosages. The dose-effect curve was sigmoidal, but between 0.5 and 8 IDU/kg maximal, minimal and mean pressure increases were proportional to the log of the dose ($p<0.01$). Biliary flow was reduced proportional to the dose for 10 min following CCK administration. The mean diminution was 58% with 0.5 IDU/kg, 70% with 1-2 IDU/kg, and 77% with 4 IDU/kg. Concurrent measurements of duodenal electrical activity demonstrated that the sphincter of Oddi is functionally independent of the duodenum. Bursts of spikes of the sphincter were independent of the duodenal spikes, and biliary pressure always increased following bursts of spikes from the sphincter of Oddi. The present study shows that CCK increases the activity of the rabbit sphincter of Oddi. This effect is different from the effect of CCK on other mammals that has been described in the literature.

3638 ANTRAL DENERVATION IN PARIETAL CELL VAGOTOMIZED DOGS: EFFECT UPON GASTRIC EMPTYING AND MOTILITY, HEIDENHAIN POUCH ACID SECRETION AND SERUM GASTRIN CONCENTRATION. (Eng.) Bone, J.; Brandsborg, O.; Brandsborg, M.; Mikkelsen, K.; Amdrup, E. (Kommunehospitalet, Arhus Univ., Arhus, Denmark). *Digestion* 15(1):1-8; 1977.

To study the effect on the hormonal phase of gastric secretion, parietal cell vagotomy and side-to-side gastroduodenostomy were performed on 10 healthy adult mongrel dogs (20-30 kg), followed by antral denervation (AD) 3 weeks later. Gastric emptying rate and motility were evaluated radiologically immediately before and 3 weeks after AD. Following AD, the stomach became enlarged and atonic; "circus movement" of the duodenal loop and antral motility ceased. Mean emptying time was 126.60 ± 12.05 min before and 111.30 ± 15.02 min after AD (difference not significant). Heidenhain pouch (HP) acid secretion increased 23-202% following AD ($p\leq 0.05$); mean post-fast (18 hr) HP acid secretion also increased significantly following AD ($p<0.01$); 5-hr food-stimulated HP acid secretion increased 33-241% from 1.74 ± 0.42 mEq H^+/5 hr before to 3.57 ± 0.77 mEq H^+/5 hr after AD ($p<0.01$). No significant differences occurred in food-stimulated or fasting serum gastrin concentrations before and after AD. Factors other than gastrin must be responsible for increase in HP response to food after AD.

3639 CORRELATION BETWEEN INTESTINAL MOTILITY AND ELECTRICAL ACTIVITY. (Fre.) Eloy, R.; Lambert, A.; Le Huan, J.; Jaeck, D.; Grenier, J. F. (INSERM U-61, avenue Moliere, F 67200 Strasbourg-Hautpierre, France). *Biol. Gastroenterol. (Paris)* 9:309; 1976.

3660 INHIBITION OF VAGALLY INDUCED GASTRIN RELEASE BY SOMATOSTATIN IN CATS. (Eng.) Uvnas-Wallensten, K.; Efendic, S.; Luft, R. (Karolinska Inst. and Hosp., Stockholm, Sweden). *Horm. Metab. Res.* 9(2):120-123; 1977.

The possibility of an inhibitory effect of somatostatin on vagally stimulated gastrin release was studied in 11 anesthetized cats. Antral gastrin release during electrical stimulation of the vagus nerve was determined in the gastric venous outflow by simultaneous recording of gastrin concentration and blood flow. Two vagal stimulations at the same frequency and duration (5 Hz for 10 min) caused similar amounts of gastrin release in the same cat; the mean gastrin output after the second stimulation was 107% of the first. The infusion of somatostatin (0.5 µg/kg/min) reduced vagally induced gastrin release to a mean level of 39% of the control value. The gastrin release induced by stimulations with 2 and 5 Hz was antagonized to a similar degree. The basal gastrin output was also reduced to about 40% of the control value during somatostatin infusion. The results may indicate a physiological role of somatostatin in the modulation of gastrin release.

3661 NEUTRAL GLYCEROGLUCOLIPIDS [sic] OF THE HUMAN GASTRIC CONTENT.

(Eng.) Slomiany, A.; Slomiany, B. (New York Medical Coll., New York, NY. 10029). *Biochem. Biophys. Res. Commun.* 76(1):115-120; 1977.

Two neutral glycolipids (A and B) were isolated from human gastric secretion using DEAE-Sephadex, silicic acid, and thin layer chromatography. Further characterization by means of gas-liquid chromatography revealed that major glyceryl ether fractions in both glycolipids were glyceryl-monohexadecyl, glyceryl-monooctadecyl, and glyceryl-monoeicososyl ether. The diglyceride portion of both A and B consisted of glyceryl-1-octadecyl, glyceryl-1-eicosyl, and glyceryl-2-hexadecyl ethers. Major fatty acids in A were docosanoate, octadecanoate, and eicosanoate, and in B, octadecanoate, eicosanoate, and hexadecanoate. The authors suggest that A is a monoalkyl-monoacyl glyceryl hexaglucoside and that B is a monalkyl-monoacyl-glyceryl octaglucoside. Glyceroglucolipids have not previously been reported in mammalian secretions.

3662 BIOSYNTHESIS OF SECRETABLE GLYCOPROTEINS OR MUCINS OF THE G.I. TRACT OF THE RAT.

(Eng.) Waldron-Edward, D.; Decaens, C.; Bader, J. P.; Robert, A. M.; Robert, L. (McGill Univ., Donner Building, Montreal, Canada). *Pathol. Biol. (Paris)* 24(8):531-536; 1976.

To study the fractions of glycoproteins, cells from rat gastric mucosal scrapings were isolated from previously secreted mucin by centrifugation (fraction I) and cultured viable cells were incubated at $^{35}Na_2SO_4$ or 5 µCi ^{14}C-1-L-fucose. Labeled mucin, synthesized and secreted during incubation, was removed by a second centrifugation (fraction II), and a subsequent pronase treatment removed tissue bound glycoprotein (fraction III). With ^{14}C-U-D-glucose at least 63% of the total incorporated radioactivity was released into fraction II as high molecular weight glycoproteins. Paper chromatography showed that, aside from labeling in galactose and hexosamine residues, the polysaccharide moiety of the secretable glycoprotein was labeled in the terminal fucose. Cells incubated in $^{35}Na_2SO_4$ incorporated 58% of the radiosulfate into secretable material, probably glycosaminoglycans, in fraction II and 21% in tissue-bound fraction III. ^{14}C-fucose was incorporated mainly into fraction II, more slowly than ^{14}C-U-D glucose. Puromycin, added to culture medium, depressed ^{14}C-U-D-glucose incorporation into fraction III, although incorporation into fraction II was unaffected. Actinomycin D also depressed incorporation into fraction III, but incorporation into fraction II was slightly stimulated. Puromycin decreased uptake of radiolabeled sulfate in fraction II by 58% and in fraction III by 44%.

3663 THE INFLUENCE OF ACETYLSALICYLIC ACID (ASPIRIN) ON GASTRIC MUCOSAL CONTENT OF ENERGY-RICH PHOSPHATE BONDS.

(Eng.) Jorgensen, T. G.; Weis-Fogh, U. S.; Olesen, H. P. (Inst. Experimental Research in Surgery, Univ. Copenhagen, Copenhagen, Denmark). *Scand. J. Clin. Lab. Invest.* 36(8):771-777; 1976.

The effect of short-term and long-term ingestion of aspirin (acetylsalicylic acid) on the morphology of the gastric mucosa and on gastric mucosal content of adenosine nucleotides was tested in 30 miniature swine. Tissue biopsies of corpus and pylorus gland areas, obtained through upper median laparotomy and gastrostomy, were evaluated for AMP, ADP, and ATP content before and after aspirin administration for 2 hr (short-term) or during a period varying from 5 to 12 weeks (long-term). In the short-term study, six groups of three to six pigs received 10 g aspirin in: 200 ml tap water (pH 3.4), 0.3 ml NaOH (pH 4.6), 0.1 N HCl (pH 1.0), or in no liquid. Adenosine phosphate was significantly ($p<0.05$) lower in aspirin-treated animals than in the controls (tap water only [pH 5.7] alone or with 0.1 N HCl), although no change occurred when aspirin was given without liquid. This decrease was greater ($0.025<p<0.05$) in pyloric gland area tissue than in corpus gland area tissue. A significant decrease in availability of high energy phosphate bonds calculated by formula (ATP + 1/2 ADP)/(ATP + ADP + AMP) occurred in pyloric gland area following ingestion of aspirin suspension at pH 1.0 (decrease 0.11, $0.01<p<0.05$), indicating the importance of an acid environment in aspirin-induced damage. In the long-term study, two pigs received 1.5 g aspirin in tablets b.i.d. for 5 weeks, two pigs received 2.5 g b.i.d. for 12 weeks, and two pigs received placebo tablets. Adenosine nucleotides decreased in all aspirin-treated pigs; corpus gland area total adenylate was lower than in placebo ($0.001<p<0.005$) and nontreated ($0.02<p<0.025$) pigs, and pyloric gland area adenylate was lower than in nontreated pigs ($0.01<p<0.02$). Gastric mucosa after 5 weeks of aspirin intake showed minor erosions and petechial bleeding and after 12 weeks, ulcerations or deep erosions penetrating the muscularis mucosa.

3664 ETHANOL-INDUCED CHANGES IN GASTRIC MUCOSAL CONTENT OF CYCLIC AMP AND ATP IN THE RAT.

(Eng.) Puurunen, J.; Hiltunen, K.; Karppanen, H. (Dept. Pharmacology, Univ. Oulu, SF-90220 Oulu 22, Finland). *Eur. J. Pharmacol.* 42(1):85-89; 1977.

The effect of gastric perfusion with a 10% ethanol solution was studied in urethane-anesthetized rats. After a 40-min perfusion, gastric acid secretion was inhibited, but 80% of the normal output was restored within 60 min after saline was substituted for the alcohol. The cyclic AMP content of the superficial mucosa, which contains most of the acid secreting parietal cells, dropped from 13.6 to 9.4 pmol/mg protein after the alcohol perfusion. The ATP content decreased from 6.9 to 5.4 pmol/mg protein. In whole mucosa, neither cyclic AMP nor ATP levels changed after ethanol perfusion. The lower values of AMP and ATP in the superficial mucosa were due to a decreased synthesis of the nucleotides, not to leakage from the parietal cells. These results suggest that ethanol-induced inhibition of gastric acid secretion may be partly due to the lowering of AMP and ATP levels in the gastric mucosa.

3665 EFFECTS OF ETHANOL ON BICARBONATE-STIMULATED ATPase, ATP, AND CYCLIC AMP IN CANINE GASTRIC MUCOSA.

(Eng.) Tague, L. L.; Shanbour, L. L. (Univ. Texas Medical Sch. Houston, Houston, TX 77025). *Proc. Soc. Exp. Biol. Med.* 154(1):37-40; 1977.

The effects of ethanol on enzymes implicated in gastric active transport (Mg^{2+}- and $Mg^{2+}HCO_3^-$ ATPases), as well as ATP and cyclic AMP, were evaluated in canine gastric mucosa. The activities of Mg^{2+}- and $Mg^{2+}HCO_3^-$-stimulated ATPases were not altered at concentrations below 10% ethanol, but were significantly inhibited (by 96%) with 15% and 20% ethanol. Tissue slice incubations with 20% ethanol showed significantly decreased ATP concentrations at 10, 20, and 30 min, $p<0.05$. Exposure of the dog gastric mucosa *in vivo* to 20% ethanol produced a significant decrease in ATP content (44%) but did not alter the cyclic AMP level. These studies suggest that the ethanol-produced decrease in gastric ATP content may be involved in the inhibition of active ion transport observed with ethanol, but that cyclic AMP is probably not involved.

3666 ACTIVATION OF RAT GASTRIC MUCOSAL ADENYLYL CYCLASE BY SECRETORY INHIBITORS.

(Eng.) Thompson, W. J.; Chang, L. K.; Rosenfeld, G. C.; Jacobson, E. D. (Univ. Texas Medical Sch., P.O. Box 20708, Houston, TX 77025). *Gastroenterology* 72(2): 251-254; 1977.

The stimulation of rat gastric mucosal adenylyl cyclase activity by three gastric secretory inhibitors (prostaglandins, secretin, and catecholamines) was studied. Prostaglandin (PG) E_1, E_2, A_1, and A_2 stimulated gastric corpus mucosal membrane adenylyl cyclase activity by 265%, 257%, 220%, and 188%, resp. PGE_1 ($K_a \approx 8$ μM) affected the maximum velocity but not the affinity of the enzyme for ATP, and maximum PGE_1 activation was not affected by histamine H_1- or H_2-receptor antagonists. 5'-Guanylyl-diphosphoimide [Gpp(NH)p], but not guanosine triphosphate, stimulated both the basal and PGE_1-stimulated adenylyl cyclase activities, although the percentage stimulation by maximal PGE was the same with or without Gpp(NH)p. NaF stimulation was also additive to that of PGE_1. Secretin also stimulated gastric mucosal adenylyl cyclase activity ($K_a \approx 30$ nM). Maximal secretin activation was not additive to that of PGE_1, suggesting a coupling to the same adenylyl cyclase catalytic site. These studies suggest that mucosal membranes may contain β-adrenergic receptors. The adenylyl cyclase activating agents used, PGE_1, secretin, and the catecholamines, are all known inhibitors of gastric acid secretion, suggesting a possible involvement of cyclic AMP in the inhibition of acid secretion in the rat stomach.

3667 LACK OF CAFFEINE STIMULATION OF GASTRIN RELEASE IN MAN.

(Eng.) Wright, L. F.; Gibson, R. G.; Hirschowitz, R. I. (Fitzsimmons U.S. Army Hosp., Denver, CO 80240). *Proc. Soc. Exp. Biol. Med.* 154(4):538-539; 1977.

Experiments were carried out in seven duodenal ulcer patients and eight normal controls to determine whether an aberration in gastrin release is responsible for the greater gastric secretory responsiveness of duodenal ulcer patients to caffeine. In two patients and two controls, gastric juice was collected for 1 hr before and the 3 hr during the infusion of caffeine benzoate (80 mg/hr for 2 hr followed by 320 mg/hr for 1 hr, i.v.); blood samples were taken before and after 1, 2, and 3 hr of infusion. All subjects had a two- to threefold dose-responsive increase in both acid and pepsin, but the serum gastrin concentration did not increase above the mean fasting level (50-65 pg/ml) in any subject. In six controls and five duodenal ulcer patients, 250 mg of caffeine was administered p.o. and blood was drawn at 0, 15, 30, 60, and 90 min. Small but significant increases of the equal magnitude in serum gastrin were seen in both groups. The results indicate that caffeine does not stimulate gastric secretion through gastrin release.

3668 GASTRIN RELEASE AND HCl SECRETION INDUCED BY ELECTRICAL VAGAL STIMULATION IN THE CAT.

(Eng.) Uvnas-Wallensten, K. (Dept. Pharmacology, Karolinska Institutet, Stockholm, Sweden). *Acta Physiol. Scand.* (Suppl. 438):3-39; 1976.

The vagally-induced release of gastrin and the antral gastrin of the cat were characterized quantitatively and qualitatively and the relation of peripheral gastrin levels to HCl secretion during vagal stimulation was investigated. Vagal stimulation caused a nearly immediate increase in gastrin release (2-3 Hz). The release mechanism underwent fatigue easily (output declined after 2-3,000 impulses of 3-4 Hz had been delivered) and required 15-20 min for full recovery. The output from unilateral stimulation ranged from 7,600 to 58,000 pg gastrin. The release response to consecutive stimulation remained constant for each cat, if sufficient recovery time was allowed. The release mechanisms stimulated by the two vagi are independent of each other; when one vagus has been fatigued, stimulation of the contralateral one will cause optimal gastrin release. Bilateral stimulation produced a response twice as large as that caused by unilateral stimulation. The basal gastrin level (50,000 pg) and vagally-induced gastrin level (64,000) were about 1% of the total antral gastrin content (60 μg). There was no relation between the peripheral gastrin levels and the acid secretory responses induced by vagal stimulation. Evidence suggests that the formation of gastric juice may be linked to gastrin elimination. Clearance of gastrin was observed in the corpus during acid secretion. The clearance of gastrin from corporeal blood, in comparison to the vagally-induced gastrin secretion, was sufficient to affect significantly the peripheral gastrin levels. Due to the clearance of gastrin in the secreting mucosa, the peripheral gastrin levels do not reflect the size of the vagally-induced release of gastrin. The different molecular forms of gastrin in the antral mucosa, in plasma, and in gastric juice were investigated by gel filtration on Sephadex columns. The antral mucosa contained mainly component III, with 5% and 1% of components II and I, resp. Only components III and IV were found in cat plasma. In gastric juice, the main gastrin resembled component III, in sulfated and unsulfated forms, with small amounts of component IV. Additionally, some common features of vagal release mechanisms for gastrin, insulin, and glucagon were investigated. Atropine blocked the vagally-induced release of all three substances.

3669 EFFECTS OF ORAL CALCIUM GLUCONATE ON GASTRIC ACID SECRETION AND SERUM GASTRIN CONCENTRATION IN MAN. (Eng.) Brodie, M. J.; Ganguli, P. C.; Fine, A.; Thomson, T. J. (Stobhill General Hosp., Glasgow, G21 3UW, Scotland). *Gut* 18(2):111-114; 1977.

The effect of the ingestion of a neutral calcium salt on gastric acid production and serum gastrin concentration was studied in man. Fifteen men without gastrointestinal disease received a single p.o. dose of 4.46 mmol calcium gluconate at pH 5.6. There was a significant rise in acid output from 30-90 min after the calcium was given ($p<0.005$) compared with the basal hourly collection. The serum gastrin level 30 min after calcium administration was significantly raised ($p<0.001$), but no correlation could be demonstrated between the acid and gastrin responses. Serum calcium levels were unchanged throughout. An equimolar dose of magnesium sulfate had no such effects. This study suggests that the intragastric administration of calcium results in independent release of gastric acid and gastrin from the gastric mucosa.

3670 EFFECT OF FUNDUSECTOMY ON SERUM AND ANTRAL GASTRIN LEVELS IN RATS. (Eng.) Tatsuta, M.; Itoh, T.; Okuda, S.; Tamura, H.; Yamamura, H. (Center for Adult Diseases, Osaka, 3-3, Nakamichi 1-choma, Higashinari-ku, Osaka 537, Japan). *Gastroenterology* 72(1):78-81; 1977.

An experimental model (fundusectomy) for hypergastrinemia was established in male Wistar rats, and the mechanism of this model was investigated. Fundusectomy significantly decreased both basal gastric acid secretion (0.022 ± 0.129 mEq/4 hr versus 0.247 ± 0.043 mEq/4 hr in controls) and tetragastrin (500 μg)-stimulated secretion (0.151 ± 0.029 mEq/4 hr versus 0.464 ± 0.041 mEq/4 hr in controls). Fundusectomy significantly increased total antral gastrin (719.1 ± 153.3 ng versus 1178.4 ± 92.9 ng in controls, $p<0.001$). In addition, the fasting serum gastrin level was increased almost 3.5-fold by fundusectomy ($p<0.001$), and food-stimulated serum gastrin was increased to 517.5 ± 91.0 pg/ml, in comparison with 166.8 ± 22.0 pg/ml in controls. The rise in fasting serum gastrin was inhibited by antral acidification, suggesting that decreased acidity caused postfundusectomy hypergastrinemia. Experimental fundusectomy provides a useful experimental system for the increase of antral gastrin and for the production of hypergastrinemia.

3671 EFFECTS OF SYNTHETIC SECRETIN ON GASTRIC SECRETION IN MAN. (Eng.) Petersen, H.; Berstad, A.; Myren, J. (Ullevaal Hosp., Oslo, Norway). *Acta Hepatogastroenterol. (Stuttg.)* 23(4): 288-291; 1976.

Studies were carried out in five healthy subjects to determine if synthetic secretin stimulates gastric acid and pepsin secretion, as has been reported for natural porcine secretin. The subjects received pentagastrin (2 μg/kg hr) i.v. alone or in combination with synthetic secretin (2 U/kg hr). Secretin inhibited acid secretion by 17% and stimulated pepsin secretion by 49%. These results indicate that the effects on gastric secretion are properties of secretin itself.

3672 EVIDENCE THAT SECRETIN DOES NOT HAVE DIRECT ANTITROPHIC EFFECTS ON THE RAT STOMACH. (Eng.) Wiseman, D. A.; Johnson, L. R. (Univ. Texas Medical Sch., Houston, TX 77030). *Proc. Soc. Exp. Biol. Med.* 153(2):277-279; 1976.

The effects of synthetic secretin on stomach weight, on biochemical characteristics of the oxyntic glandular mucosa, and on gastrin levels were studied in Sprague-Dawley rats to determine if secretin inhibits stomach growth. Twelve rats received synthetic secretin (100 U/kg) s.c. every 8 hr for 14 days. In comparison with controls, no differences in the weight of the stomach, oxyntic gland area, antrum, or oxyntic glandular mucosa were noted in the secretin-treated animals. The DNA, protein, and pepsinogen contents as well as the carbonic anhydrase activity of the oxyntic glandular mucosa were unaffected, and there were no changes in antral or serum gastrin levels. It is concluded that secretin does not have an antitrophic effect on the rat stomach and that the previously reported antitrophic effect of secretin on this tissue was due to the inhibition of pentagastrin.

3673 EFFECT OF FUNDIC DISTENSION ON GASTRIC ACID SECRETION IN MAN. (Eng.) Grotzinger, U.; Bergegardh, S.; Olbe, L. (Sahlgren's Hosp., Goteborg, Sweden). *Gut* 18(2):105-110; 1977.

The effect of distension of the fundus and body of the stomach on gastric acid secretion was studied in 26 patients with duodenal ulcer and in 6 healthy subjects. Graded distension produced by inflating a rubber balloon to volumes of 150, 300, and 600 ml resulted in significant sequential increments of acid output (mean values of 2.8, 4.4, and 5.6 mmol/15 min, resp., compared to a basal level of

1.7 mmol/15 min; $p<0.01$). The secretory response outlasted stimulation by at least 1 hr. In both groups of subjects, the highest acid output obtainable with fundic distension amounted to just above 50% of the maximum secretory response evoked by the i.v. infusion of pentagastrin. A significant correlation was found between the peak secretory rates observed during fundic distension and after pentagastrin stimulation. It is concluded that distension of the oxyntic gland area in man is a potent stimulus for gastric secretion of acid, and that patients with duodenal ulcer are no more sensitive to this stimulus than healthy subjects.

3674 FATE OF TRITIATED GASTRIN IN THE RAT AFTER TOTAL GASTRECTOMY AND AFTER ANTRUM TRANSPOSITION TO COLON. (Fre.) Gislon, J.; Millat, B.; Bonfils, S.; Girma, J. P.; Morgat, J. L.; Fromageot, P. (INSERM U-10, Hopital Bichat, 170, Boulevard Ney, F 75877 Paris Cedex 18, France). *Biol. Gastroenterol. (Paris)* 65(5):199-205; 1976.

To study the role of the stomach during the first phase of acid secretion after gastrin stimulation, the distribution and fate of tritiated gastrin (90 Ci/mmol) were studied in male Wistar rats (200-250 g) 2 weeks after transposition of the antrum to the colon (ACT rats) or after total gastrectomy (Gect rats). The half-life of gastrin was not affected by the surgery. The increased fundic fixation of gastrin found in ACT rats, compared to normal controls, could be due to increased parietal cell mass. Both ACT and Gect rats showed increased retention of radioactivity in the kidney. In ACT rats, this may be due to the hypersecretory activity of the fundus, leading to accelerated turnover of hormone to the kidney. In Gect rats, the lack of target organ could lead to more rapid renal catabolism of the radioactive hormone.

3675 EFFECT OF DUODENAL ACIDIFICATION ON PENTAGASTRIN-STIMULATED ACID SECRETION IN PAVLOV POUCH CATS. (Eng.) Svensson, S. O.; Emas, S. (Karolinska Hosp., Stockholm, Sweden). *Scand. J. Gastroenterol.* 11(Suppl. 42):55-59; 1976.

The effect of endogenous duodenal acidification on pentagastrin- and 2-deoxy-D-glucose (2DG)-stimulated acid secretion was studied in Pavlov pouch cats that also had gastric fistulae. Endogenous acidification of the duodenum was produced by closing the gastric fistula. This procedure did not alter the mean peak of 2DG-stimulated acid secretion, the mean curve of the acid response, or the time to reach the peak acid output. With the gastric fistula open, the peak pentagastrin-stimulated acid output from the Pavlov pouch occurred independently of the dose during the third to sixth 15-min periods. During infusion, acid secretion slowly declined with time both in the pouch and in the main stomach to 50-60% of the peak output at the end of the infusion. Closing the gastric fistula significantly reduced the early response to pentagastrin only at the 2 and 8 μg doses. The decline of acid secretion with
time was less pronounced than with the fistula o
Closing the fistula increased the late (11th and
12th 15-min periods) dose-response curve. It is
concluded that "physiological" amounts of HCl in
intact duodenum do not inhibit either pentagastr
or vagally stimulated acid secretion from the in
nervated oxyntic glands in conscious cats.

SECRETION AND METABOLISM

Pancreas

3724 MODIFICATION IN THE PATTERN OF THE PANCREATIC RESPONSE TO REPEATED HORMONAL STIMULATION IN THE RAT. (Fre.) Mongeau, R.; Morisset, J. (Universite de Sherbrooke, Sherbrooke, Quebec, Canada, J1K 2R1). *Gastroenterol. Clin. Biol.* 1(3):243-248; 1977.

Pancreatic protein synthesis after single and repeated hormonal stimulation of the exocrine pancreas was studied in male Sprague-Dawley rats anesthetized with urethane. Rats received single or repeated i.v. injections of a mixture of the hormones cholecystokinin-pancreozymin (8 U/kg) and secretin (10 U/kg) or isotonic solution (placebo). After sacrifice, the pancreas was incubated *in vitro*, and amylase secretion and the incorporation of ^{14}C-phenylalanine into total proteins were determined. Animals that were stimulated once showed a two- to threefold increase ($p<0.01$) in amylase secretion, whereas those with a repeat injection 15 min after the first one had a four- to fivefold ($p<0.005$) increase in amylase secretion with a simultaneous decrease in ^{14}C-phenylalanine incorporation as compared with controls. When the animals were sacrificed 30 min or more after the last injection, no significant difference between controls or test animals was noted. The results indicate that the pancreatic response to a cholinergic or hormonal stimulus is translated in the first phase by a decrease of protein synthesis concomitant to an increase of enzymatic secretion and, in a second phase, by an increase of protein synthesis at the time the secretion of enzymes has or seems to have ended.

3725 METHOD FOR DIRECT MEASUREMENT OF CHOLERESIS AND SECRETORY FUNCTION OF THE EXOCRINE PANCREAS DEMONSTRATED BY SODIUM DEHYDROCHOLATE. (Ger.) Tauschel, H. D.; Herrmann, M. (Godecke AG, Abteilung Zellbiologie, Mooswaldallee, 7800 Freiburg/Brsg., W. Germany). *Arzneim. Forsch.* 27(2b):475-480; 1977.

An experimental method is presented for direct and simultaneous measurement of choleresis and secretory function of the dog pancreas stimulated by secretin (ST) and bile secretion induced by sodium dehydrocholate (SD). Both drugs were administered to anesthetized mongrel dogs, either i.v. into the femoral vein or intraduodenal into the distal duodenal segment after ligature. The drugs were given via a canula immediately after ligature of the pylorus in trials without duodenal perfusion. The pancreas and duodenal perfusates were collected and stored at -70 C for determination of alkaline phosphatase, α-amylase, bicarbonate, total bilirubin, cholesterol, bile acids, lipase, protein, and trypsin activity. After ST, 3 U/kg i.v., a rapid steep increase and decrease of the extinction curves were noted with a similar sharp protein peak plus an increase of α-amylase and lipase activities. The bile secretion maximum was reached 6 min after ST application. The bicarbonate, protein, and enzyme activities peaked at different times. A choleretic effect was noted 3.5 min following SD, 10 mg/kg i.v. and 100 mg/kg intraduodenal, with a steep rise and fall of the extinction curve. The extinction maximum after intraduodenal application occurred later than with i.v. dosing. The absorption peaks at 280 nm UV correlated well with the protein values. Bile acids, bilirubin, and cholesterol levels also increased as did enzyme activities. All bile parameters, except bile volume, were twofold greater after intraduodenal application than after i.v. injection and returned to baseline 190 min after the former mode of application, which indicated a rapid renal clearance for ST. In conclusion, this method allows the study of kinetic problems and time-dependent reactions of choleresis, ST-induced pancreatic secretion, and SD-induced bile secretion.

3726 ETHANOL METABOLISM IN RAT PANCREAS. I. PRESENCE AND LEVEL MODIFICATIONS OF ETHANOL OXIDIZING SYSTEMS. (Fre.) Clemente, F.; Durand, S.; Laval, J.; Thouvenot, J. P.; Ribet, A. (INSERM U-151, C.H.U. Rangueil, Bat. L3, F 31400 Toulouse Cedex, France). *Gastroenterol. Clin. Biol.* 1(1): 39-48; 1977.

Ethanol (ET) oxidizing systems were studied in the pancreas of male Wistar rats given water *ad libitum* containing ET (20 mg/100 ml) for 10-12 weeks. Another group of 15 rats was treated with ET for 2 yr; only 2 controls and 3 ET-treated rats survived 2 yr. A histological study of pancreas from sacrificed ET-treated animals and controls showed little structural alterations. In homogenates of pancreas tissue, no difference between controls and ET-treated rats was seen with respect to alcohol dehydrogenase levels. Catalase, NADPH-reductase, or cytochrome oxidase activity in the pancreas did not change. Microsomal ET oxidation activity and NADPH-oxidase were not detected. In subcellular fractions of pancreatic tissue samples, cytochrome C-oxidase and succinodehydrogenase levels were significantly lower in the internal membrane of mitochondria in ET-treated animals, which was not apparent in comparison of homogenates. No signs of chronic pancreatitis were observed in three animals treated for 2 yr. Hepatocytes showed marked steatosis after prolonged treatment.

3727 ENZYME CONTENTS, ENZYME EXCRETION AND ULTRASTRUCTURE OF THE PANCREAS AFTER CHRONIC METHADONE ADMINISTRATION IN RATS. (Fre.) Roze, C.; Camilleri, J. P.; Vaille, C.; Chariot, J.; La Tour, J.; Souchard, M.; *et al.* (Hopital Bichat, 170, bd Ney, F 75877 Paris Cedex 18, France). *J. Pharmacol.* 7(4):479-490; 1976.

No significant differences in pancreas weight, DNA, RNA, total protein, amylase, and lipase contents were noted between controls and Wistar rats treated with DL-methadone (DM), 5-15 mg/kg daily, s.c., for 15-30 days. The total body weight of DM-treated animals was slightly less than controls (228 g as compared with 254 g). Concentrations of trypsin and chymotrypsinogen were significantly elevated in the pancreas of rats treated with DM. Excretion of protein and amylase increased but not as significantly as trypsinogen and chymotrypsinogen content, when enzyme levels of pancreatic secretion were measured after rats had acute pancreatic fistulas under urethane anesthesia. Enzyme concentrations of pancreatic tissue were lower in DM-treated animals after 7 hr of anesthesia than in controls. Microscopic examination of the pancreas revealed no interstitial alterations, edema, or cellular infiltrates following DM treatment. Signs of moderate hypersecretion were observed ultrastructurally. Although pancreatic stimulation due to prolonged DM treatment was expected, the role of anesthesia has yet to be elucidated.

SECRETION AND METABOLISM

Hepatobiliary Tract

3749 EXOCRINE PANCREAS UNDER EXPERIMENTAL CONDITIONS. II. IN VITRO FORMATION OF PARACRYSTALLINE STRUCTURES AND ITS FUNCTIONAL CONSEQUENCES. (Eng.) Metz, J.; Forssmann, W. G. (Inst. Anatomy, Univ. Heidelberg, Im Neuenheimer Feld 307, D-6900 Heidelberg, W. Germany). *Cell Tissue Res.* 173(2):221-235; 1976.

The different steps of the secretory process in exocrine pancreatic cells of male Wistar rats were investigated under the influence of different para-chloro-phenylalanine (pCPA)-dependent experimental conditions. Two different approaches were used. First, the effect of pCPA-pretreatment of rats, and second, the effect of varying pCPA concentrations in the incubation medium on the secretory process in untreated pancreatic lobules were studied. Formation of paracrystalline inclusions was induced *in vitro* in pancreatic lobules incubated in Krebs-Hepes-buffer (KHB) solution containing high concentrations of pCPA or even a restricted number of natural amino acids and other amino acid analogues. Every exocrine cell contained numerous paracrystalline inclusions when 1×10^{-2} M pCPA was used. Investigations with homogenates of pancreatic tissue, liver, and muscle after incubation with KHB plus 1×10^{-2} M pCPA showed paracrystals in the lumen of the endoplasmic reticulum of the pancreatic homogenates. No crystal formation was observed after incubation of liver and muscle homogenates alone. Electron microscopically, a significant degranulation of the exocrine pancreatic cells was found in the pCPA-pretreated cells during the incubation period. There was no indication that the paracrystalline structures in the endoplasmic reticulum were altered quantitatively or qualitatively in these cells. The incorporation of ^{3}H-leucine into pancreatic protein was inhibited in a dose-dependent manner, and it occurred to a greater extent after addition of pCPA to the incubation medium than was observed with pCPA-pretreated pancreatic lobules. This difference suggests that inhibition of protein synthesis is due to the presence and antagonistic effect of pCPA, although pCPA is not incorporated into proteins. It is concluded that the functional process of the exocrine pancreas is changed by pCPA both *in vitro* and *in vivo*.

3750 THE INFLUENCE OF THE POSITION OF THE OXYGEN DISSOCIATION CURVE ON OXYGEN-DEPENDENT FUNCTIONS OF THE ISOLATED PERFUSED RAT LIVER. III. STUDIES AT DIFFERENT LEVELS OF ANAEMIC HYPOXIA. (Eng.) Bakker, J. C.; Gortmaker, G. C.; De Vries-Van Rossen, A.; Offerijns, F. G. J. (Netherlands Red Cross Blood Transfusion Service, P.O. Box 9190, Amsterdam, Netherlands). *Pfluegers Arch.* 368(1/2):63-70; 1977.

The influence of a 2,3-diphosphoglycerate (DPG)-induced displacement of the oxygen dissociation curve on O_2 consumption, bile flow rate, venous pO_2, lactate/pyruvate (L/P) ratio, and β-hydroxybutyrate/acetoacetate (β-OH/Acac) ratio in rat liver at different levels of anemic hypoxia was studied. The rat livers were perfused with fresh and DPG-depleted human RBC at different hematocrit levels (30-2.5%). A decrease in oxygen supply brought about by decrease of hematocrit caused a decrease in O_2 consumption, bile flow rate, and venous pO_2, and a decrease in the L/P and β-OH/Acac ratios. The DPG content of RBC did not influence the above-mentioned parameters during severe anemic hypoxia. At O_2 supply levels between 1 and 2 ml/min/liver, venous pO_2 values were significantly higher ($p<0.01$) with the fresh than with the DPG-depleted RBC perfusates. β-OH/Acac ratios were slightly lower ($p<0.05$) with the fresh RBC perfusates at O_2 supply values of about 2.2, 1.4, and 0.9 ml/min/liver than with the DPG-depleted RBC perfusates. No differences were found in O_2 consumption, bile flow rate, or L/P ratio between fresh and DPG-depleted RBC under either normal and hypoxic conditions. These results indicate that DPG does not play a compensatory role during conditions of severe anemic hypoxia, but it may play such a role during mild anemia.

3751 SYNTHESIS AND LOCALIZATION OF α-FETO-PROTEIN IN REGENERATING MICE LIVER. (Rus.) Engelgardt, N. V.; Poltoranina, V. S.; Lazareva, M. N.; Perova, S. D.; Gleiberman, A. S. (USSR Acad. Medical Sciences, Moscow, USSR). *Biull. Eksp. Biol. Med.* 82(10):1251-1254; 1976.

The synthesis and localization of α-fetoprotein (AFP) in regenerating liver was observed after CCl_4 poisoning in male SWR mice and after partial hepatectomy in male C3NA mice, 3-4 months of age. The change in the AFP fluorescence in the liver sections was compared with AFP blood serum levels. Cells were tested for the specific antigen of the bile capillaries. In the liver sections, cells containing the AFP were found 24 hr after exposure to CCl_4. On the second day after CCl_4 poisoning, the number of hepatocytes containing the AFP and the intensity of their fluorescence sharply increased. The number of AFP hepatocytes peaked on the third day, but at no time did they represent more than 5-7% of the total hepatocyte population. AFP levels in the blood showed a parallel increase and decrease after poisoning. To exclude the possibility that AFP penetrates regenerating cells as a result of membrane damage, hepatocytes were observed for IgM immunofluorescence. The majority of the hepatocytes with AFP did not have IgM. Morphologically, AFP hepatocytes did not differ from the other hepatocytes and retained bile capillary antigen on their surface.

3752 THE EFFECT OF VAGOTOMY ON HEPATIC REGENERATION IN RATS. (Eng.) Lamar, C., Jr.; Holloway, L. S., Jr. (Veterans Admin. Hosp., 109 Bee St., Charleston, SC 29403). *Acta Hepatogastroenterol.* 24(1):7-10; 1977.

Liver regeneration was studied in male Holtzman rats that had undergone a bilateral cervical vagotomy to determine if the vagus plays a significant role in the control of hepatic regeneration. A 66% hepatectomy or a sham operation was carried out at the same time as vagotomy. Bilateral vagotomy significantly reduced the incorporation of ^3H-thymidine into liver nuclear DNA at 24 hr in comparison with controls (25,380 disintegrations per minute [DPM]/mg DNA versus 3,700 DPM/mg DNA, $p<0.01$). Ornithine decarboxylase (ODC) activity was significantly less at 4 hr after partial hepatectomy in vagotomized rats (176 versus 309 ODC U; $p<0.01$), but was similar to that in controls at 8 and 24 hr. The data suggest that the liver parenchyma receives vagal innervation and that this innervation may play a role in the control of liver regeneration.

3753 AN ^{125}I RADIOIMMUNOASSAY FOR PRIMARY CONJUGATED BILE SALTS. (Eng.) Spenney, J. G.; Johnson, B. J.; Hirschowitz, B. I.; Mihas, A. A.; Gibson, R. (Dept. Medicine, Univ. Alabama in Birmingham, Birmingham, AL). *Gastroenterology* 72(2):305-311; 1977.

The synthesis of cholylglycylhistamine and its use in the development of an ^{125}I-immunoassay for bile salts are reported. The new assay has increased antibody titers over those used in tritium-based assays from 1:500 to as much as 1:80,000, and it has reduced the complexity and expense of radioimmunoassay. The immunoassay was found to measure predominantly the conjugated bile salts since the representative estrogenic, androgenic, and adrenal steroids did not cross-react. The concentrations used were adequate to measure both physiological and pathological conditions. The sensitivity of the radioimmunoassay has been maintained, with the least detectable amount being 0.5 pmol bile salts per assay tube. Normal values for bile salts in human sera are 3.47 ± 2.16 nmol/ml. The assay is not monospecific, and the specificities depend in part on the technique used to separate the bound and free bile salt fractions. Dextran-coated charcoal is the preferred method of separating bound and free fractions, because it not only gives greater specificity, but is easier, more rapid, and more reproducible than the polyethylene glycol method. There seems to be little reason to favor a monospecific assay over one that quantitates several bile salts. As in other radioimmunoassays, it is critically important for specificities to be carefully defined. For research applications in which quantitation of single bile salts is essential, monospecific antibodies or initial purification of samples would be necessary.

3754 BILIARY REABSORPTION OF CHOLATE SODIUM, GLYCOCHOLATE SODIUM, AND TAUROCHOLATE SODIUM FROM THE RAT BILIARY TREE AFTER RETROGRADE INTRABILIARY INJECTION. (Eng.) Dammann, H. G. (I. Medizinische Universitatsklinik, Universitat Hamburg, Martinistr. 52, D-2000 Hamburg 20, W. Germany). *Klin. Wochenschr.* 54(17):845-847; 1976.

The biliary reabsorption of cholate sodium, glycocholate sodium, and taurocholate sodium was demonstrated after retrograde intrabiliary injection in rats. The percent recoveries found in the bile during the first time interval (0-2.5 min) were significantly higher in rats in which 20 nmol of the bile salts were administered in a total retrograde volume of 20 µl (57.1 ± 4.0-62.0 ± 2.2%) than in rats that received 20 nmol of the bile salts in a total retrograde volume of 40 µl (32.3 ± 2.2-39.8 ± 1.7%). When bile flow was started immediately after retrograde administration, significantly higher percent recoveries of ^{14}C-glycocholate and ^{14}C-taurocholate were found after retrograde injection (39.1 ± 2.6 and 39.8 ± 1.7%) in comparison to ^{14}C-cholate (32.3 ± 2.2%). An occlusion time of 30 sec after injection resulted in significantly reduced percent recoveries of ^{14}C-glycocholate and ^{14}C-taurocholate (30.2 ± 2.3 and 26.7 ± 1.7%) in comparison to experiments in which bile flow was started immediately. Conjugation of cholate to glycine and taurine may have some effect on the extent of biliary reabsorption of this bile acid. Biliary reabsorption appears to have an important influence on the biliary excretion of bile salts.

3755 FORMATION OF ω-MURICHOLIC ACID AND THE FECAL EXCRETION OF BILIARY ACIDS IN THE RAT.

(Fre.) Sacquet, E.; Leprince, C.; Riottot, M.; Mejean, C.; Leglise, P. (Laboratoire des Animaux sans Germes du C.N.R.S., C.N.R.S., 78350 Jouy-en-Josas, France). *C. R. Acad. Sci.* [*D*] *(Paris)* 284 (7):557-559; 1977.

The excretion of fecal bile acids was compared in holoxenic rats and in axenic rats supplied with a modified intestinal flora by giving them bile-free holoxenic fecal material that had been heated to 70 C for 10 min. The modified axenic rats excreted more total bile acids, which consisted mainly of ω-muricholic acid and a small amount of hyodeoxycholic acid. The holoxenic rats produced less total bile acids, even though they consumed more food, and the proportions of ω-muricholic acid and hyodeoxycholic acid were reversed. These results suggest that a decrease in bacterial 7β-hydroxylases causes an increase in ω-muricholic acid, which in turn results in an increase in total bile acid fecal excretion.

3756 EFFECTS OF SINGLE INGESTION OF SEVERAL BILE ACIDS OR CHOLESTYRAMINE ON ^{14}CO$_2$ OUTPUT IN [26 ^{14}C] CHOLESTEROL-FED RATS.

(Eng.) Mathe, D.; Chevallier, F. (Laboratoire de Physiologie de la Nutrition, Universite Paris-Sud, Batiment 447, F 91405 Orsay Cedex, France). *Biochimie* 58(10):1293-1295; 1976.

The rate of cholesterol metabolism after a single p.o. dose of bile acid or cholestyramine was studied in male Wistar rats fed a diet containing 0.05% cholesterol and 30 μCi/100 g of ^{14}C-cholesterol. During days 3-5 of the experiment, the daily ^{14}CO$_2$ output was decreased 10-37% by the addition to the diet of a bile salt (sodium taurocholate, 10-80 mg; sodium glycocholate, 80 mg; cholic acid, 60 mg; sodium taurochenodeoxycholate, 80 mg; deoxycholic acid, 30 mg; hyodeoxycholic acid, 60 mg; or ursodeoxycholic acid, 60 mg). Taurocholate, cholic acid, and deoxycholic acid produced the largest decreases--32%, 35%, and 37%, resp. During the latter part of the experiment (lasting 3-8 days), ^{14}CO$_2$ production was increased.

3757 FORMATION AND INHIBITION OF LYSOLECITHIN IN HUMAN GALLBLADDER BILE.

(Eng.) Sjodahl, R.; Tagesson, C. (Dept. Surgery, Linkoping Univ., Linkoping, Sweden). *Acta Chir. Scand.* 142(5):395-399; 1976.

The phospholipase activity of homogenized human gallbladder epithelium was examined by assaying the formation of ^{14}C-lysolecithin from ^{14}C-lecithin. Incubation was carried out in diluted human gallbladder bile. The surface activity of lysolecithin was assessed in two ways: (1) by its ability to disperse liposomes containing ^{3}H-cholesterol in the lipid film and ^{14}C-glucose trapped from an aqueous solution and to alter the amounts of sedimenting and nonsedimenting isotopes and (2) by its ability to lyse RBC and to prevent pelleting of hemoglobin. The epithelial homogenate catalyzed the hydrolysis of lecithin to lysolecithin in bile. No lysolecithin was produced in the bile when the homogenate was omitted. Lysolecithin was able to lyse RBC both in isotonic (0.15 M) saline and in diluted (1:2) human gallbladder bile, but the bile contained an inhibitor of this reaction (assuming that the bile did not alter the sensitivity of the cells). In saline, no hemoglobin was pelleted (total lysis occurred) when lysolecithin exceeded 20-30 μg/ml, but in bile, the lysolecithin had to exceed 3,000-5,000 μg/ml to prevent hemoglobin from pelleting. No effect on ^{3}H-cholesterol or ^{14}C-glucose sedimentation was caused by lysolecithin at 50 μg/ml or less, but at 500 μg/ml (corresponding to 15% of the total phospholipid in the system), the amount of ^{14}C-glucose sedimenting increased markedly from about 50% to 90% and the amount of ^{3}H-cholesterol sedimenting decreased from about 60% to 50%, with a further decrease to about 15% at 5,000 μg/ml lysolecithin. The liposome bilayers are relatively stable to rather high concentrations of lysolecithin.

3758 DEGRADATION OF CHYLOMICRON REMNANT CHOLESTERYL ESTER BY RAT HEPATOCYTE MONOLAYERS. INHIBITION BY CHLOROQUINE AND COLCHICINE.

(Eng.) Floren, C. H.; Nilsson, A. (Dept. Physiological Chemistry, Univ. Lund, Lund, Sweden). *Biochem. Biophys. Res. Commun.* 74(2):520-528; 1977.

The effects of colchicine and of chloroquine on cholesteryl ester (CE) degradation were examined to test whether microtubules and lysosomal enzymes may participate in the degradative process. Rat hepatocytes in monolayer culture take up and hydrolyze the CE of isolated chylomicron remnant particles. When equal amounts of CE were added as remnant particles and as native chyle or chylomicrons, much more CE was taken up and degraded in the incubation with remnants than in the incubation with native compounds. Similar observations were made with perfused rat liver, in which uptake of remnants prepared from radioiodinated chylomicrons was shown to be much more efficient than uptake of the native chylomicrons. The structure of the intact tissue is not necessary for a selective uptake of remnants compared to uptake of native chylomicrons. This fact suggests that what occurs during the conversion of chylomicrons to remnant particles is an increase in the affinity of the lipoprotein particles for hepatocytes. It is this phenomenon in addition to a decrease in size that facilitates the filtration of particles into the space of Disse. Colchicine inhibits the hydrolysis of chylomicron remnant CE taken up by cells. The remnants might be taken up in endocytic vesicles that do not undergo fusion with primary lysosomes at a normal rate in the presence of antimicrotubular agents. Final conclusions about the mechanism of chylomicron remnant degradation *in vivo* must await further studies on the intact animal.

3759 MORPHOMETRIC STUDY OF ALCOHOL-HIGH LIPID INTAKE IN RATS.

(Fre.) Oudea, M. C.; Lostanlen, D.; Collette, M. (E.R.A. 334, U.E.R. de Medecine, 1 rue Gaston-Veil, F 44035 Nantes, France). *Biol. Gastroenterol. (Paris)* 9(2):139-146; 1976.

The effects of chronic alcohol ingestion on the ultrastructure of the rat liver were studied morphometrically and compared to changes seen in isolated hepatic mitochondria (HM). Rats were fed a high-fat diet plus ethanol; controls were given dextrine maltose instead of alcohol. At the highest dose, the amount of ethanol corresponded to 36% of the caloric intake. Stereological studies were done according to the modified method of Weibel. Alcohol-treated rats had a larger liver than the livers of control rats, and liver specimens showed moderate steatosis without giant HM. These rats had a significantly greater increase in the surface volume of the granular endoplasmic reticulum and total and mean volumes of the cell nuclei and HM. No significant difference was seen between treated and control rats with respect to HM diffusion spaces and mean diameter of the HM globules. Thus, HM changes observed *in vivo* apparently are partly due to the surrounding cellular medium.

3760 INCREASED SUSCEPTIBILITY OF HEPATIC MITOCHONDRIA TO THE TOXICITY OF ACETALDEHYDE AFTER CHRONIC ETHANOL CONSUMPTION. (Eng.)

Matsuzaki, S.; Lieber, C. S. (Mount Sinai Sch. Medicine, New York, NY 10468). *Biochem. Biophys. Res. Commun.* 75(4):1059-1065; 1977.

Liver mitochondria from rats fed ethanol chronically were studied for impairment of hepatic mitochondrial respiration and fatty acid oxidation in the presence of physiological levels of acetaldehyde (AC). Female Sprague-Dawley rat littermates were pair-fed nutritionally adequate liquid diets with 36% of the calories as ethanol or isocaloric carbohydrates for 4-6 weeks. AC was added for final concentration of 200 µM or 1 mM after hepatic mitochondria were suspended in medium of 225 mM mannitol, 75 mM sucrose, 10 mM $MgCl_2$, 0.5 mM Na EDTA, and 10 mM phosphate buffer (pH 7.4). Mitochondria from the ethanol-treated rats had significantly decreased O_2 consumption with 3.3 mM glutamate or β-hydroxybutyrate as substrate (not with 3.3 mM succinate) in the presence of either concentration of AC. O_2 consumption was depressed in mitochondria from control rats in the presence of high AC levels. O_2 consumption was measured under "state 3" conditions induced by addition of 675 nmol of ADP. Fatty acid oxidation of mitochondrial was studied by measuring CO_2 production at 37 C using 1-^{14}C-labeled palmitic and oleic acids. Rates of CO_2 production were slightly lowered in mitochondria from livers of ethanol-treated rats. AC, 200 µM, significantly depressed rates of fatty acid oxidation as measured by CO_2. This study supports the theory of a "vicious cycle" induced by chronic alcohol consumption whereby higher AC levels lead to mitochondrial injury leading to decreased capacity to metabolize AC and even further elevation of AC levels.

3761 CHANGES IN PROTEIN METABOLISM IN THE MYOCARDIUM AND LIVER OF RATS UNDER THE EFFECT OF TOXIC DOSES OF ALCOHOL. (Rus.)

Kazantseva, G. P. (Rjazansk Medical Inst., Rjazansk, USSR). *Patol. Fiziol. Eksp. Ter.* (3):62-63; 1976.

Alterations of protein metabolism in the myocardium and the liver after intragastric administration of a single toxic dose of ethanol (6 ml/kg of 96% alcohol) to 275 of male rats were investigated. Rats were sacrificed after 3, 5, 24, and 48 hr after administration of alcohol and the protein synthesis was traced with i.p. ^{35}S-methionine. The results were compared with those of a control group of rats, given the same amount of water. In both the liver and the myocardium, a decrease in uptake of ^{35}S-methionine in the mitochondria and the reduction of total protein in the myocardium was observed as early as 3 hr after ethanol administration. After 5 hr, a marked acceleration of protein synthesis was noted. By the end of the second day, protein metabolism was, on the whole, normal. The changes in protein metabolism as a result of the effect of a toxic dose of alcohol testify to a definite histotoxic influence of ethanol on the liver and myocardium.

3762 EFFECT OF A HYDROCHOLERETIC AGENT (ZANCHOL) ON STEROL METABOLISM IN RATS. (Eng.)

Raicht, R. F.; Cohen, B. I.; Eliav, B. B.; Mosbach, E. H.; Zimmon, D. S. (Manhattan Veterans Admin. Hosp., 408 First Ave., New York, NY 10010). *Gastroenterology* 72(3):507-509; 1977.

The effects of γ-oxo-γ-(8-fluoranthene)butyric acid (Zanchol) on sterol metabolism was studied in male Sprague-Dawley rats. The rats received 5-10 µCi DL-2-^{14}C-mevalonolactone, and an experimental diet containing 0.4% Zanchol was started several hr later. The animals received this diet for 14 days. The Zanchol-fed animals had significantly larger livers (15.4 g ± 2.0 versus 11.2 g ± 2.0, $p<0.025$), and electron microscopy revealed smooth endoplasmic reticulum proliferation and decreased glycogen in the liver cells. Bile cholesterol concentrations were not significantly different from those of controls. Zanchol feeding increased acidic steroid output by 71% and cholesterol synthesis by 265%. Cholesterol absorption was decreased 27%. In controls, the percentage of biliary cholic acid plus its metabolite (deoxycholic acid) was 59.5% ± 6.4. The percentage of chenodeoxycholic acid plus its metabolites was 40.5% ± 6.4. Zanchol feeding increased the percentage of cholic acid and its metabolite to 77.4% ± 7.5 ($p<0.025$), and the percentage of chenodeoxycholic acid and its metabolites was reduced to 22.6% ± 7.5. These changes were associated with the disappearance of the muricholic acids from the bile. These results suggest selective enhancement of cholic acid synthesis by stimulation of 7α-hydroxy-4-cholesten-3-one-12α hydroxylase. Zanchol markedly changes sterol metabolism in rats.

3763 THE EFFECT OF SORBITOL INFUSION ON THE COURSE OF ACUTE TOXIC HEPATITIS. (Rus.)

Abesadze, A. I.; Danielova, E. M.; Dgebuadze R. G.; Katamadze, N. G. (Inst. Hematology Tblisi, USSR). *Patol. Fiziol. Eksp. Ter.* (5):54-57; 1976.

The effect of i.v. sorbitol (10 ml/kg) on the course of acute toxic hepatitis induced by five p.o. doses of CCl_4, 0.2 mg/kg in 1/1 dilution of sunflower oil, administered over 48-hr period in 12 dogs of both sexes was studied. Two series of experiments were carried out: (1) five infusions of sorbitol simultaneously with CCl_4 (6 dogs) and (2) five infusions of sorbitol started 15 to 17 days after beginning p.o. CCl_4 (6 dogs). Separately, changes in liver function and hemostasis activity in acute toxic hepatitis were studied in seven control dogs. Simultaneous infusions of sorbitol and CCl_4 prevented development of severe hepatitis and profound and prolonged disturbances in hemostasis activity and hepatic function. Pathological changes in indices of hepatic function peaked between the 10th and 20th day after CCl_4 and sorbitol while in the control series complete restoration of these indices was not observed on the 30th day. No difference in prothrombin time was found; increase of the blood fibrinogen and unconjugated heparin was insignificant. The preventive action of sorbitol was less pronounced in the second series of experiments. Liver function was restored on the 30th day after CCl_4. The results suggest that infusions of sorbitol have significant liver detoxifying activity.

3764 THE EFFECT OF LYSOSOME TRITON WR 1339 LOAD ON ^{14}C-ALBUMIN DISTRIBUTION IN THE LIVER OF RATS WITH CHRONIC HEPATITIS. (Rus.) Korolenko, T. A.; Titova, V. C. (Novosibirsk Medical Inst., Novosibirsk, USSR). *Biull. Eksp. Biol. Med.* 82(7):816-819, 1976.

The protective effect of the lysosomotropic detergent Triton WR-1339 was studied in male Wistar rats with CCl_4-induced hepatitis. The animals were divided into two groups: rats in group A were inoculated with Triton WR-1339 (85 mg/100 g, i.p.) 4 hr prior to the first exposure to CCl_4, and rats in group B received detergent (dose as before) 1 day after the last inhalation with CCl_4. On days 1, 3, and 7 after the last inhalation, rats were injected with ^{14}C-albumin (0.25 mg/100 g, i.v.), and 30 min later, they were sacrificed. The liver uptake of the labeled protein was significantly increased in the animals with CCl_4-induced hepatitis (5.70 ± 1.25%, compared to 1.80 ± 0.13% in intact animals). Prior inoculation with detergent (group 1) did not affect the uptake of ^{14}C-albumin (4.10 ± 0.25%), while subsequent inoculation (group B) significantly inhibited the protein uptake (1.40 ± 0.30%). The maximum concentration of ^{14}C-albumin was recorded in the lysosome fraction, which might be indicative of the selective role of the lysosomes from the Kuppfer cells in the restoration of the liver function in chronic hepatitis.

3765 CHOLECYSTECTOMY AND CARCINOMA OF THE COLON. AN EXPERIMENTAL STUDY. (Eng.) Werner, B.; de Heer, K.; Mitschke, H. (Univ. Hosp., Hamburg, Martinistrasse 52, D-2000 Hamburg 20, W. Germany). *Z. Krebsforsch.* 88(3):223-230; 1977.

The influence of cholecystectomy on the development of carcinoma of the colon was investigated in female NMRI mice. The incidence of colonic carcinoma induced by the s.c. injection of 1,2-dimethylhydrazine (DMH) after cholecystectomy was significantly increased; after 10 weekly injections of 15 mg/kg DMH, 70% of the animals with cholecystectomy developed carcinoma. Only 16% of the mice with similar treatment but without cholecystectomy had carcinoma. The cocarcinogenic effect of cholecystectomy may be due to the increased production of secondary bile salts by the colonic bacteria and the lack of resorptive function of the gallbladder for some carcinogenic substances passing through the liver.

3766 UTILIZATION OF DIETARY AMINO ACIDS FOR ENERGY PRODUCTION IN NEONATAL RAT LIVER. (Eng.) White, P. K.; Miller, S. A. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA). *Pediatr. Res.* 10(3):158-163; 1976.

SECRETION AND METABOLISM

Intestine

3824 DIFFERENTIATION AND AGING OF THE INTESTINAL MUCOSA OF THE RAT. I. MORPHOLOGICAL, ENZYME-HISTOCHEMICAL AND DISC ELECTROPHORETIC ASPECTS OF THE PRENATAL AND POSTNATAL DIFFERENTIATION OF THE INTESTINAL MUCOSA. (Eng.) Hohn, P.; Schafer, A.; Gabbert, H. (Pathological Inst., Johannes Gutenberg Univ., Mainz, W. Germany). *Mech. Ageing Dev.* 6(1): 35-51; 1977.

Morphological and enzymatic properties of the mucosa of the small and large intestine of the rat were studied from the fetal to the adult stage in order to delineate phases of maturation and aging in the intestine. Electron microscopic, histochemical, and electrophoretic analyses were done for four phosphatases and seven dehydrogenases. The study showed that enzymatic changes occurred synchronously with morphological differentiation, and that development could be described in four stages; (1) the 19th to the 21st fetal day is a period of increasing enzyme activity in the enterocytes and formation of giant lysosomes in the ileal epithelium; (2) during the first 2 weeks of life, the lysosomes complete their development, but enzymatic activity remains nearly the same as on day 21; (3) during the first half of the third week of life, various qualitative and quantitative enzyme changes take place, in addition to the development of an epithelial population in the ileum that lacks lysosomes; (4) and development of the intestine is completed by the middle of the fourth week, as the adult stage is reached.

3825 EFFECT OF BISACODYL ON THE STRUCTURE AND FUNCTION OF RODENT AND HUMAN INTESTINE. (Eng.) Saunders, D. R.; Sillery, J.; Rachmilewitz, D.; Rubin, C. E.; Tytgat, G. N. (Dept. Medicine RG-20, Univ. Washington, Seattle, WA 98195). *Gastroenterology* 72(5):849-856; 1977.

The effect of bisacodyl on intestinal structure and function was investigated in male Sprague-Dawley rats and in humans. Net water transport was measured under steady state conditions *in vivo* during single pass infusions of intestinal segments. Each segment served as its own control. Bisacodyl inhibited water absorption in rat jejunum, ileum, and colon. The degree of inhibition was linearly related to the logarithm of the bisacodyl concentration over the range 0.05-2.0 mg/100 ml. In human jejunal segments, bisacodyl (1 mg/100 ml) caused net water secretion. Bisacodyl (5 mg every 6 hr, p.o.) increased ileostomy output by 15% in five patients with established ileostomies. By light microscopy, bisacodyl (2 mg/100 ml) erased cytoplasmic and nuclear detail within surface absorptive cells of rat intestine. By electron microscopy, the involved cells contained sparse and abnormal cytoplasmic organelles and chromatin-deficient nuclei. These results suggest that the laxative effect of bisacodyl is related to its ability to inhibit intestinal water absorption. Reduced absorption may be secondary to changes in surface absorptive cells.

3826 CELL KINETICS IN THE SMALL INTESTINE OF SUCKLING RATS. I. INFLUENCE OF HYPOPHYSECTOMY. (Eng.) Yeh, K. Y. (Dept. Biology, Washington Univ., St. Louis, MO 63130). *Anat. Rec.* 188(1):69-76; 1977.

Cell kinetics were examined in the duodena of intact Wistar NLR rats at 6, 16, and 22 days of age, and of hypophysectomized rats at 22 days. In intact rats, the crypt population per villus increased over 10-fold, the greater part of the increase occurring late in the third week. The labeling index did not differ between 6 (28.3%) and 16 (27.6%) days, but increased to 37.8% at 22 days. Generation time did not differ between 6 (18.0 hr) and 16 (17.7 hr) days, but fell to 10.8 hr at 22 days by shortening of both the presynthetic and synthetic phases. Acceleration of cell migration rate between 18 and 19 days of age resulted in shortening of cell transit time from 7 days in rats younger than 18 days to 2 days in those older than 18 days. When rats were hypophysectomized at 6 days, the duodenal crypt population per villus at 22 days was comparable to that of intact rats at 16 days. The labeling index at 22 days was 19% lower than that of intact rats at 6 days. Generation time at 22 days was slightly shortened by a decrease of the presynthetic phase, but the duration of 15.5 hr was 43% longer than in intact rats at the same age. Despite the small crypt population and the low cell production rate, the cell transit time in 22-day-old hypophysectomized animals is only 3 days.

3827 ULTRASTRUCTURAL FEATURES OF REGIONAL DIFFERENCES IN CHYLOMICRON SECRETION BY RAT INTESTINE. (Eng.) Sabesin, S. M.; Clark, S. B.; Holt, P. R. (Univ. Tennessee Coll. Medicine, Memphis, TN 38163). *Exp. Mol. Pathol.* 26(2):277-289; 1977.

The effects of prolonged intraduodenal triolein perfusion on intestinal fat absorption were studied in the rat small intestine to investigate the ultrastructural features of regional differences in chylomicron secretory capacity. Using conditions in which intraluminal triolein concentrations were high enough to saturate the mechanism for fat uptake, the proximal segments reached a steady state of uptake and chylomicron secretion within 1 hr, whereas triglycerides accumulated progressively in the distal epithelial cells. After 1 or 4 hr of perfusion with [1-^{14}C]triolein, the mucosal triglyceride content was much greater in distal than in proximal segments (43.8 versus 67.6 mEq fatty acid/g wet weight at 1 hr; 55.0 versus 203.5 mEq/g at 4 hr), and electron microscopy disclosed many more and larger intracellular fat droplets in the distal absorptive cells. Six hours after stopping the 4-hr perfusion, many distal cells were still filled with large fat droplets, whereas the proximal cells were devoid of fat. In comparison to proximal intestine, triglycerides accumulated in distal segments following direct segmental triolein perfusion, and electron microscopy disclosed large intracellular fat droplets similar to those observed after intraduodenal triolein perfusion. The ultrastructural observations suggest that fat accumulation, in the distal segments, is due to a relatively decreased capacity for chylomicron release. These studies suggest an intrinsic difference between proximal and distal intestine in fat absorption, which may reflect regional differences in cellular function such as membrane availability for the final assembly and secretion of chylomicrons.

3828 EFFECT OF NEPHRECTOMY AND ENTERECTOMY ON PLASMA CLEARANCE OF INTRAVENOUSLY ADMINISTERED DIPEPTIDES IN RATS. (Eng.) Adibi, S. A.; Krzysik, B. A. (Gastrointestinal and Nutrition Unit, Montefiore Hosp., Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15213). *Clin. Sci. Mol. Med.* 52(2): 205-213; 1977.

The plasma clearance of i.v. administered dipeptides was studied in bilaterally nephrectomized, enterectomized, and sham-operated rats. During the first 5 min after their introduction, plasma levels of glycyl-L-leucine (GL) and glycylglycine (GG) were higher in nephrectomized than in control rats, but there were no significant differences thereafter. Glycylsarcosine (GS) clearance was impeded after nephrectomy, and its half-life in the plasma was prolonged from 7.6 to 52.0 min. GL and GG were not found in the tissues of sham-operated rats (muscle, liver, intestinal mucosa, and renal cortex), but GS was found in all four tissues. GG was found in the muscle, liver, and mucosa of nephrectomized rats, but GL was present in muscle only. Enterectomy did not affect the half-life of GG in plasma, but allowed its accumulation in the renal cortex, muscle, and liver. It is concluded that the kidneys and intestine are important but not essential in the plasma clearance of easily hydrolyzed dipeptides. Clearance of dipeptides that are poorly hydrolyzed by body tissues, such as GS, appears to be performed in the kidneys only.

3829 EFFECTS OF VARIOUS CARBOHYDRATES ON THE ACTIVITY OF ENZYMES IN THE BRUSH BORDERS OF THE JEJUNAL MUCOSA. INCREASED PHOSPHATASE ACTIVITY. (Fre.) Dupuis, Y.; Fournier, A.; Fournier, P. (Metabolisme mineral des Mammiferes [E.P.H.E.], Faculte de Pharmacie, 92290 Chatenay-Malabry, Paris, France). *C. R. Soc. Biol. (Paris)* 170(4):739-744; 1976.

The effects of sorbitol (SB: 200 mM) or disodium hydrogen phosphate (DHP: 50 mM) on enzyme activities in the brush borders of the rat jejunum were studied. Jejunal mucosa was obtained surgically from anesthetized rats, treated with butanol and then centrifuged. SB exerted only a slight effect on glycosidase activity, whereas DHP induced marked but moderate activity. SB had no effect on aminopeptidase activity; the effect of DHP on this enzyme could not be ascertained. SB increased alkaline phosphatase activity markedly, but DP reduced it significantly. In another experiment in which aqueous mucosal extracts were prepared in tris buffer and treated with butanol, a significant increase in phosphatase activity was also induced by mannitol, dulcitol, inositol, D-glucose, D-xylose, L-arabinose, lactose, and raffinose. The effect of SB and DHB on the phosphatase activity in rat jejunum was similar to that observed in Ca absorption.

3830 ABSORPTION AND METABOLISM OF FRUCTOSE IN THE SMALL INTESTINE OF CONVENTIONAL AND GERM-FREE PIGLETS IN VITRO. (Eng.) Talafantova, M.; Kolinska, J. (Inst. Microbiology, Novy Hradek, Praha 4, Czechoslovakia). *Folia Biol. (Praha)* 23(1):76-80; 1977.

The uptake and metabolism of D-fructose was studied in jejunal loops from conventional and germ-free piglets during their development. The intracellular fructose concentration after a 30-min incubation with 1 mM fructose was highest (although not exceeding the concentration of fructose in the incubation medium) in the intestine of the newborn pig, in comparison with the concentration in 1-, 2-, 3-, 7-, 8-, and 13-day-old pigs. With increasing age, a decline in intracellular fructose concentration was found, the sharpest decrease being observed between 0 and 2 days of age. The main metabolic product of fructose was lactic acid. Lactate production from endogenous sources within the small intestine was highest in the intestinal loops from the newborn conventional pigs, while lactate production in the germ-free pigs increased with increasing age, following the drop between 0 and 2 days of age.

3831 JEJUNAL SUCRASE IN RATS: TYPES OF RESPONSE TO STIMULATION WITH SUCROSE. (Por.) Soares, F. C.; Collares, E. F.; do Rosario, M.; Brasil, L. (Hospital das Clinicas, Rua Bernardino de Campos, 1000, 14100 Ribeirao Preto, Sao Paulo, Brazil). *Arq. Gastroenterol.* 13(2):89-96; 1976.

The specific activity of sucrase was measured in three different segments of rat jejunum following direct and indirect stimulus with 70% dietary sucrose. Adult male Wistar rats, stabilized on standard diets for 7 days, were divided into six groups (11/group); one group was sacrificed immediately, while the remaining groups were fasted for 24 hr. A 10-cm segment of small intestine was then excised and joined at both ends to the abdominal wall. The intestine was repaired by end-to-end anastomosis, and the isolated segment remained inside the abdominal cavity. Surgery was followed by a 72-hr fast and then a 24- or 72-hr diet with or without sucrose; all rats consumed about 12 g of food/day. One group was sacrificed immediately after the fast period. Sucrase activity was determined in homogenized tissues, including the isolated segment, and in the two 10-cm segments on either side of the anastomosis. The 24-hr sucrose stimulus produced a rise in sucrase activity in one intact segment over activity in the isolated segment. All three segments showed rises in sucrase activity after 72-hr sucrose. The delayed response of the enzyme in the isolated segment, which occurred despite lack of direct exposure to sucrose, is not understood; it may be related to cell migration and may be under hormonal or nervous system control. Fasted rats and those receiving diet without sucrose showed similar levels of sucrase activity.

3832 INHIBITION OF INTESTINAL GLUCAGON-LIKE IMMUNOREACTIVITY (GLI) SECRETION BY SOMATOSTATIN IN MAN.

(Eng.) Marco, J.; Hedo, J. A.; Villanueva, M. L. (Clinica Puerta de Hierro, Universidad Autonoma de Madrid, San Martin de Porres 4, Madrid 35, Spain). *J. Clin. Endocrinol. Metab.* 44(4):695-698; 1977.

To investigate the influence of somatostatin on intestinal glucagon-like immunoreactivity (GLI) secretion, the GLI secretion in response to p.o. glucose was determined in six gastrectomized men during an i.v. somatostatin infusion. Sixty minutes after the start of a somatostatin (9 μg/min following the injection of a 250 μg bolus dose) or saline infusion, GLI secretion was stimulated with glucose (1.75 μg/kg, 25% solution). Glucose stimulated a 340% and a 150% elevation in circulating GLI, using antisera 78J and R-8, resp. Somatostatin did not modify fasting GLI concentrations but completely abolished the GLI response to glucose ingestion, and termination of the somatostatin infusion was followed by a rapid and significant increase in plasma GLI levels. The inhibitory effect of somatostatin on beta cell function was evidenced by a slight reduction from basal insulin levels (-2 μU/ml, $p<0.01$) and by the absence of insulin response to glucose; a dramatic insulin rebound occurred upon somatostatin withdrawal. Somatostatin also lowered fasting glycemia (-23 mg% at 0 min, $p<0.001$); during its infusion, the elevation of blood sugar after p.o. glucose was delayed. The data demonstrate that somatostatin inhibits GLI secretion in man, and that it retards glucose absorption.

3833 POTASSIUM SECRETION BY COLONIC MUCOSAL CELLS AFTER POTASSIUM ADAPTATION.

(Eng.) Fisher, K. A.; Binder, H. J.; Hayslett, J. P. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *Am. J. Physiol.* 231(4):987-994; 1976.

Studies of fluid and electrolyte movement, potential difference, and Na-K-ATPase activity were performed in rat colon and jejunum. Male Sprague-Dawley rats fed 2.6 mEq K/gm diet for 7 days were compared to a control group fed 0.13 mEq K/gm. A marked increase in both urinary (27.2 ± 1.54 mEq/24 hr, $p<0.001$) and fecal (0.42 ± 0.05, $p<0.001$) excretion of potassium was reported. In the colon, chronic potassium loading increased potassium secretion from 0.8 ± 0.2 to 3.9 ± 0.9 μEq/min/g tissue $p<0.01$) and increased the potential difference from 27 ± 5.0 to 54 ± 2.6 mV ($p<0.001$), lumen negative, as Na-K-ATPase activity increased in homogenates from 5.0 ± 0.5 to 11.4 ± 1.0 μM Pi/mg protein/hr ($p<0.001$). The 5'-nucleotidase activity was not affected. In contrast, there was no change in potential difference, potassium movement or Na-K-ATPase activity in the jejunum of potassium-loaded rats. Colonic movement of water, sodium, and chloride was similar in the control and potassium-loaded rats. Electrical resistance and ^{3}H-inulin clearance did not change in potassium-loaded rat colon. Adrenalectomy significantly ($p<0.05$) decreased the Na-K-ATPase activity, the potential difference (12.8 ± 1.2 mV compared to the control value of 26.3 ± 5.0 mV), and the potassium secretion in animals maintained on a normal intake of potassium. However, increased dietary intake of potassium significantly increased Na-K-ATPase activity and potential difference in adrenalectomized animals. It is suggested that the colon shares with the mammalian distal tubules of the kidney the capacity to adjust potassium transport to meet metabolic needs. Na-K-ATPase may be important in transepithelial potassium movement.

3834 THE EFFECT OF MICROFLORA ON THE INTESTINAL METABOLISM OF L-THREONINE IN RATS.

(Fre.) Combe, E.; Debras, E. (Laboratoire d'Etude du Metabolisme azote, I.N.R.A., Theix, 63110-Beaumont, France). *C. R. Soc. Biol. (Paris)* 170(2):368-374; 1976.

The effect of microflora on the intestinal metabolism of L-threonine (Th) was studied in holoxenic and axenic Wistar CR rats. Two hours after injection of 10 μCi ^{14}C-Th, i.p., blood samples were taken from the aorta, stomach, and small intestine of anesthetized rats. The cecum and large intestine were frozen. Radioactivity (RA) was determined by liquid scintillation spectrometry. The mean amount of RA expired in the CO_2 of both groups of rats did not differ. However, RA was raised significantly in the digestive tract of axenic animals compared with holoxenic animals. RA was highest in the small intestine and lowest in the cecum and large intestine of holoxenic rats, where the microflora synthesized its own proteins from labeled digestive material. Trichloroacetic acid-soluble tissue from holoxenic rats showed that the free labeled Th level was greater than that of amine and nonamine compounds. However, in axenic rats the activity of the latter compounds in the digestive contents was greater than that of free Th.

3835 DEMONSTRATION OF A VITAMIN B_{12} BINDER IN PANCREATIC JUICE: EFFECT ON THE INTESTINAL UPTAKE OF VITAMIN B_{12}.

(Eng.) Von der Lippe, G.; Andersen, K. J.; Schjonsby, H. (Univ. Bergen, Haukeland Sykehus, Bergen, Norway). *Scand. J. Gastroenterol.* 11:807-812; 1976.

Studies were conducted to determine whether a vitamin B_{12}-binding principle was present in human and rat pancreatic juices, and to study the influence of this binder on intestinal uptake of vitamin B_{12}. Determination of vitamin B_{12}-binding capacity and the gel filtration of human and rat pancreatic juices demonstrated a vitamin B_{12} binder different from gastric intrinsic factor (IF). Unsaturated

B_{12}-binding capacity was also demonstrated in the gastric mucosa of the rat and in saliva, bile, gastric juice, and duodenal juice from patients (1 with duodenal ulcer, 2 with chronic alcoholism, and 1 with chronic pancreatitis). In the presence of human IF antibody, the B_{12}-binding capacity of rat and human pancreatic juices was unchanged, whereas, the B_{12}-binding capacity of rat gastric mucosa extract and of human gastric juice markedly decreased. There was a small decrease in the B_{12}-binding capacity of bile, saliva, and duodenal juice in the presence of human IF antibody. The presence of vitamin B_{12} binders in rat pancreatic juice and human pancreatic and duodenal juices was confirmed by gel filtration. Vitamin B_{12} binders in human and rat pancreatic juices had no effect on the intestinal uptake of $^{57}CoB_{12}$ bound to IF *in vivo* and *in vitro*. This fact suggests that under the experimental conditions the pancreatic vitamin B_{12} binder does not influence the intestinal uptake of vitamin B_{12}.

3836 JEJUNOILEAL BYPASS IN THE TREATMENT OF RATS WITH EXPERIMENTAL OBESITY. COMMUNICATION II: LONG-TERM EVOLUTION OF SOME BIOHUMORAL PARAMETERS. (Ita.) Armellini, F.; Belligoli, A. GENERAL

3859 BALANCE STUDY OF TWENTY TRACE ELEMENTS DURING TOTAL PARENTERAL NUTRITION IN MAN. (Eng.) Jacobson, S.; Wester, P. O. (Dept. Surgery, Huddinge sjukhus, 141 86 Huddinge, Sweden). *Br. J. Nutr.* 37(1):107-206; 1977.

The balances of 20 trace elements (Ag, As, Au, Br, Cd, Co, Cr, Cs, Cu, Fe, Hg, La, Mo, Ru, Sb, Sc, Se, Sm, W, and Zn) were determined in four adult male patients parenterally fed a special diet that included a fat emulsion and an electrolyte solution containing Fe, Zn, Mn, Cu, F, I, Ca, and Mg. The trace elements were analyzed by an ion exchange technique based on neutron activation followed by gamma spectrometry. The amounts of trace elements added corresponded approximately to those analyzed. All other trace elements determined were unintentionally administered in the parenteral supply. Fe, Ag, Co, Cr, Cu, Sb, Sc, and W were retained, and Br, Rb, As, Au, Cd, Cs, Mo, Se, and Zn were lost. However, Zn was retained by one patient with short bowel syndrome. The serum concentration of 13 trace elements decreased during parenteral nutrition, in agreement with the corresponding balance values. FAO/WHO and other recommendations for essential, possibly essential, and unlikely to be essential trace elements for man and animals are reviewed. Admin-

tration of trace elements in long-term total
renteral nutrition is recommended.

360 WHOLE BODY ALBUMIN MASS AND DISTRIBUTION
IN RATS FED ON LOW-PROTEIN DIETS. (Eng.)
ward, W. A.; Sawyer, M. B. (MRC Dunn Nutrition
it, Dunn Nutritional Lab., Univ. Cambridge,
lton Rd., Cambridge, CB4 1XJ, England). *Br. J.
tr.* 37(1):127-134; 1977.

o groups of 5-week-old rats were fed diets
ntaining 210 g (controls) or 31 g protein/kg
d sacrificed over a 3-week period to determine
asma albumin concentration, plasma volume, and
tal vascular and extravascular albumin mass.
asma albumin concentrations were lower in rats
d the low-protein diet (27 g/l versus 33 g/l
controls at 12 days), but plasma volume was
ightly greater (51 versus 46 ml/kg at 12 days).
tal vascular albumin mass was significantly
ss in experimental animals at 8 and 20 days,
t it was significantly lower than initial
lues only at 20 days. Extravascular albumin mass
.6 versus 2.4 g/kg at 20 days) and whole-body
bumin mass (3 versus 3.8 g/kg at 20 days) were
so significantly reduced in the experimental
imals. A significant redistribution of whole-
dy albumin mass was shown by a lower ratio of
e extravascular albumin mass:vascular mass. It
concluded that plasma albumin concentration
es not indicate the real whole-body albumin losses
protein deficiency, because total vascular
bumin mass is maintained somewhat at the expense
extravascular albumin mass.

61 BIOCHEMICAL CHARACTERISTICS OF DIFFERENT
FORMS OF PROTEIN ENERGY MALNUTRITION;
EXPERIMENTAL MODEL USING YOUNG RATS. (Eng.)
ard, C. R. C.; Frangi, S. M.; Wright, P. M.;
Cartney, P. R. (Clinical Nutrition and Metabolism
it, Dept. Human Nutrition, London Sch. Hygiene
d Tropical Medicine, Keppel St., London WC1E 7HT,
gland). *Br. J. Nutr.* 37(1):1-21; 1977.

ur groups of young male rats were fed diets consis-
ng either of high protein (HP) *ad libitum,* low pro-
in (LP) *ad libitum,* HP restricted to the amount
e LP rats consumed, or HP followed by 2 days of
sting. The rats on LP or restricted AP diets
nsumed about 50% as much as the HP-fed rats,
d their body weights were about 35% and 55% of
e HP-fed rats, resp. The LP and restricted
rats had low fasting insulin levels and low
sulin:glucose ratios during glucose tolerance
sts carried out in the fourth week of the diet.
e rats were sacrificed after 4 weeks. LP rats
owed low values for hemoglobin (15% lower than
rats), plasma protein concentration, and hepatic
ucose-6-phosphatase and alanine aminotransferase
tivities, but hepatic aspartate aminotransferase
tivity was slightly increased. Plasma amino acid
ncentrations and ratios showed decreases in
anched chain amino acids, and liver fat content
s increased about 100%. Rats on the restricted
diet showed normal hemoglobin, plasma protein,
and liver fat concentrations and almost normal plasma amino acid levels. Hepatic alanine aminotransferase was increased, but the muscle enzyme was decreased. Rats fasted for 48 hr following an HP diet had high hemoglobin, plasma protein, liver fat content, and hepatic alanine aminotransferase levels and low liver glycogen and plasma alanine levels. The data indicate lowered gluconeogenesis, liver dysfunction, and essential amino acid deprivation in rats on an LP diet, features similar to those seen in kwashiorkor. Rats on a restricted HP diet had symptoms similar to those of nutritional marasmus. The authors compare their results in rats with biochemical changes observed in infant malnutrition.

3862 CAPILLARY REGIONAL BLOOD FLOWS IN DIGESTIVE ORGANS OF THE RAT UNDER URETHANE ANESTHESIA: A STUDY OF ISOPROTERENOL, PROPRANOLOL, AND SECRETIN. (Fre.) Dupont, C.; Jean, E.; Roze, C.; Wepierre, J. (Laboratoire de Pharmacodynamie, U.E.R. Chimie Therapeutique, Centre d'Etudes Pharmaceutiques, F 92290 Chatenay-Malabry, Paris, France). *Biol. Gastroenterol. (Paris)* 9(2):129-138; 1976.

The effects of i.v. infusion of isoproterenol (IS: 0.6-15 µg/kg), with or without concomitant propranolol (PR: 2 mg/kg), and secretin (SE: 0.125-0.5 U/kg) on cardiovascular hemodynamics and capillary regional blood flow in the digestive tract were studied in urethane-anesthetized rats. After IS perfusion, hypotension and tachycardia developed, but only high doses (5 and 15 µg/kg) caused a transient decrease in cardiac output (CO). Blood pressure, pulse rate, and peripheral resistance increased significantly 5 min after IS and then dropped. PR decreased CO and heart rate, but increased peripheral resistance significantly. Pretreatment with PR inhibited the effects of IS on the cardiovascular parameters. IS alone had no effect on blood flow in the salivary glands, rumen, or fundus, but it decreased the flow in the pancreas, small intestine, and liver. When PR was given prior to IS, however, blood flow in the pancreas, stomach, small intestine, and liver was increased. No cardiovascular changes were seen following treatment with SE. This agent only increased pancreatic blood flow significantly at a dose of 0.5 U/kg/min.

3863 INFLUENCE OF SMALL BOWEL MOTILITY ON ITS MICROCIRCULATION. (Fre.) Coulic, V.; Maximenkova, A.; Finikova, L. (Chaire d'Anatomie humaine, Universite de l'Amitie des Peuples P. Lumumba, Moscow, B-302, USSR). *Biol. Gastroenterol. (Paris)* 9:289-294; 1976.

Simultaneous balloonographic investigation of bowel motility and biomicroscopy of the bowel wall in rabbits, guinea pigs, and rats showed evidence of some dependence between microcirculatory processes and intestinal contractile cycles. The correlation may account in part for the pathogenesis of functional modifications seen after neuroreflectory isolation and autotransplantation of the small bowel.

GENERAL

3864 ADRENERGIC MECHANISMS IN THE HEPATIC ARTERIAL CIRCULATION OF BABOONS. (Eng.) Swan, K. G.; Kerr, J. C.; Wright, C. B.; Reynolds, D. G. (Div. General and Vascular Surgery, New Jersey Medical Sch., 100 Bergen St., Newark, NJ 07103). *Surgery* 81(3):326-334; 1977.

Injections of norepinephrine or epinephrine (0.025 μg/kg/min) in anesthetized baboons caused dose-dependent decreases in hepatic arterial blood flow. The responses were attenuated by alpha-adrenergic blockade (AAB) with phenoxybenzamine (1.5 mg/kg), but unchanged by beta-adrenergic blockade (BAB) with propranolol (0.5 mg/kg). Injections of isoproterenol (0.25 μg/kg/min) caused increases in hepatic arterial flow that were reversed to constriction at low doses of the agonist but attenuated at high doses by BAB. The extent of constriction was attenuated by AAB but not potentiated by BAB. Intrahepatic arterial infusions of epinephrine or norepinephrine were not accompanied by autoregulatory escape, and the degree of constriction was attenuated by AAB but not potentiated by BAB. Small increases in hepatic arterial blood flow (Q=70 ml/min) were caused by relatively large intrahepatic arterial infusions of isoproterenol (0.25 μg/kg), which were not potentiated by AAB but were attenuated by BAB. The results suggest a relative decrease in beta receptor activity in the hepatic arterial bed of the baboon relative to regional circulations such as the mesenteric and femoral beds. Beta receptors are relatively resistant to stimulation and blockade.

3865 THE ROLE OF GASTRIC MUCOSAL BLOOD FLOW AND H^+ BACK-DIFFUSION IN THE PATHOGENESIS OF ACUTE GASTRIC EROSIONS. (Eng.) Cheung, L. Y.; Chang, N. (Veterans Admin. Hosp., Salt Lake City, UT 84132). *J. Surg. Res.* 22(4):357-361; 1977.

The relation between ischemia and disruption of the gastric permeability barrier in the pathogenesis of acute gastric erosions was evaluated in 14 dogs. Studies were carried out on the effect of (1) hemorrhagic shock; (2) topical application of *p*-chloromercuribenzene sulfonate (PCMBS); and (3) shock plus PCMBS on total and mucosal blood flow, H^+ back-diffusion, and mucosal injury. The fractional distribution of blood flow through the layers of gastric tissue remained unchanged during control, shock, and reinfusion periods. Exposure of the mucosa to PCMBS resulted in a significant increase in H^+ back-diffusion, which was accompanied by a rise in mucosal blood flow. Hemorrhagic shock alone caused a marked mucosal ischemia without disruption of the permeability barrier. The most severe mucosal injury occurred only under experimental conditions where ischemia and increased H^+ back-diffusion were induced simultaneously. These results suggest that: (1) A cause-effect relationship does not exist between ischemia and barrier disruption in the pathogenesis of acute ulcerations; (2) mucosal blood flow may play an important role in the disposal of H^+ permeating the mucosa; and (3) the ratio of mucosal blood flow to back-diffusion of H^+ may determine the degree of mucosal injury.

3866 THE ROLES OF INTRALUMINAL OXYGEN AND GLUCOSE IN THE PROTECTION OF THE RAT INTESTINAL MUCOSA FROM THE EFFECTS OF ISCHAEMIA. (Eng.) Robinson, J. W. L.; Mirkovitch, V. (Centre Hospitalier Universitaire Vaudois, 1011 Lausanne 11, Switzerland). *Biomedicine (Express)* 27(2):60-62; 1977.

The protective actions of oxygen and glucose were evaluated in the ischemic rat intestine, using the change in phenylalanine accumulation *in vitro* to assess the extent of damage. Ileal loops were subjected to 15 min periods of ischemia by clamping both mesenteric and collateral vessels. Ischemia reduced the *in vitro* ability of the intestine to accumulate phenylalanine, from a control value of 0.643 ± 0.0355 to 0.195 ± 0.0259 μmol/100 mg wet weight. If the lumen had been flushed with an oxygenated buffer containing 0.1% glucose, there was complete protection of the mucosa, the phenylalanine uptake being 0.774 ± 0.0410 μmol/100 mg.g. No protection was afforded by a prior rinsing with a buffer saturated with nitrogen and containing no glucose. When glucose was added to the nitrogenated buffer, there was some protection (0.457 ± 0.0688 μmol/100 mg), but the phenylalanine uptake was still significantly lower than that of control loops. In the absence of glucose, the protective influence of the oxygenated buffer was attenuated, the phenylalanine level being 0.494 ± 0.0730 μmol/100 mg. A factorial analysis of variance to test the efficacy of the different agents in protecting against the effects of ischemia revealed that the effects of oxygen and of glucose are perfectly additive, each having a separate protective influence. The independent and additive actions of glucose and oxygen imply that the rat enterocyte is capable of obtaining energy supplies from two metabolic sources and, consequently, that the cellular energy levels have a role in the prevention of anoxic damage.

3867 REVERSAL OF INTESTINAL SEGMENTS FOR TREATMENT OF MALABSORPTION AFTER SMALL BOWEL RESECTION. (Ger.) Kieninger, G. (Chirurgische Universitatsklinik, Calwer Strasse 7, D-7400 Tubingen, W. Germany). *Med. Klin.* 72(13):554-559; 1977.

The effect of reversal of intestinal segments was studied in 50 guinea pigs divided into groups of 14 animals. Three groups had a 90% small bowel resection with either no reversal, primary, or secondary reversal; one unoperated group served as controls. The reversal segments, 5 or 10 cm in length, were inserted in the middle or at the end of the remaining jejunum or ileum. Parameters evaluated included weight, survival time, intestinal transit time, absorption capacity measured by expiration of $^{14}CO_2$, and determination of stool fat. Small intestine segments were also examined macroscopically and histologically. The intestinal transit time of animals with reversal of one or two 5- or 10-cm segments was 5 and 6 times greater than that of animals without reversal. The increased transit time was positively correlated to the postoperative weight gain and survival time; 12/14 animals with reversal with the ileum remnant survived and showed a normal weight development, whereas both groups without reversal died of hunger cachexia within 3 months. A marked weight gain and improvement in general condition were noted in five of six cachexic animals following a secondary reversal. Animals with intestinal segment reversal also showed a significantly higher absorptive capacity, and exhalation of $^{14}CO_2$ approached that of controls. Furthermore, these groups showed 3.1 g% of fat in stool as compared with 7.7 g% in animals without a reversal (2.0 g% in controls). After 1 yr, a significant increase in the length and width of the remaining intestine was also noted in the animals with a reversal, and histology revealed hyper-regeneration of muscle layers and mucosa. The author recommends this surgical procedure for clinical use.

3868 INFLUENCE OF EXPERIMENTAL BYPASS ON CELLULAR KINETICS AND MATURATION OF SMALL INTESTINAL EPITHELIUM IN THE RAT. (Eng.) Rijke, R. P. C.; Plaisier, H. M.; de Ruiter, H.; Galjaard, H. (Dept. Cell Biology and Genetics, Erasmus Univ. Rotterdam, P.O. Box 1738, Rotterdam, Netherlands). *Gastroenterology* 72(5):896-901; 1977.

The effect of experimental bypass on the intestinal epithelium was investigated 2-360 days after creating a Thiry-Vella fistula in male Glaxo Wistar rats. Within 7-14 days, the number of cells per villus column and, to a lesser degree, the number of cells per crypt column decreased (by 80% in the former case), and subsequently these values remained constant up to 1 yr. Radioautography showed no changes in the percentage of labeled cells per crypt column after incorporation of $[^3H]$thymidine. In addition, the relative size of the proliferative cell compartment in the crypt, the number of crypts per unit length of small intestine, and the crypt: villus ratio remained unchanged. Scintillation counting of isolated crypts from the Thiry-Vella fistulas showed that the number of cells per crypt was markedly reduced. Scanning electron microscopy revealed that the three-dimensional size of the villi was also reduced. The activities of nonspecific esterases and neutral α-glucosidase remained unchanged in crypt cells and were above control values in villus cells. The development of these biochemical characteristics of the villus cells seems to be independent of the luminal contents. It is concluded that deprivation of food passage and gastric, pancreatic, and liver secretions from a small intestinal segment causes primarily a reduction in the number of cells per crypt, which leads to a lower cell production; in turn, this is responsible for the reduction of the functional villus cell compartment.

3869 PROTECTIVE EFFECTS OF PASSIVELY TRANSFERRED IMMUNE T- OR B-LYMPHOCYTES IN MICE INFECTED WITH Salmonella typhimurium. (Eng.) Hochadel, J. F.; Keller, K. F. (Sch. Medicine, Univ. Louisville, Louisville, KY 40201). *J. Infect. Dis.* 135(5):813-823; 1977.

The relative contributions of both humoral and cell-mediated immune responses to the protection of mice against lethal infection with *Salmonella typhimurium* were compared by separating the subpopulations of lymphocytes and using these subpopulations to supplement normal animals prior to challenge. Purified populations of bone marrow-derived (B-) lymphocytes and thymus-derived (T-) lymphocytes were obtained from C3D2F1 hybrid mice shown to be immune to *S. typhimurium*. These subpopulations of lymphocytes were injected into normal mice; 4 days later the animals were challenged with a 50 LD$_{50}$ dose of *S. typhimurium*, and viable bacteria in livers, spleens, and blood were counted at various intervals after challenge. On day 8 after challenge, the mice supplemented with B-lymphocytes showed a significant decrease in the number of organisms recovered from all three sites, compared with that seen in recipients of T-lymphocytes and in controls. The mice given B-lymphocytes showed a better survival rate (65%) than mice that received only T-lymphocytes (21%) or T-lymphocyte fractions contaminated 10%-30% with B-lymphocytes (49%). These data indicate that, although the humoral response is not totally protective, it does play an important role in the suppression of the infection during its early stages.

3870 IMMUNOLOGICAL INTERACTIONS BETWEEN Trichinella spiralis AND Trichuris muris IN THE INTESTINE OF THE MOUSE. (Eng.) Bruce, R. G.; Wakelin, D. (Dept. Zoology, Univ. Glasgow, G12 8QQ, Scotland). *Parasitology* 74(2):163-173; 1977.

The immunological interactions between *Trichinella spiralis* and *Trichuris muris* were investigated in the intestine of outbred (CFLP) and inbred (NIH) mice. The inflammatory response, which is thought to be partly responsible for the expulsion of *Trichinella spiralis* from the mid-region of the small intestine, also seemed to be largely responsible for the simultaneous (i.e., early) expulsion of *Trichuris muris* from the cecum and large intestine during concurrent primary infections. The interactive expulsion operated only when the concurrent infections were timed to produce *T. spiralis* expulsion before *T. muris* expulsion would normally occur, and the effect producing early expulsion of *T. muris* persisted for several days after *T. spiralis* had been expelled. Interactive expulsion was depressed during indomethacin (0.1 mg/day, p.o.) treatment and during T-cell depletion, even though in thymectomized mice there was a delayed, partial expulsion of *T. spiralis*. These results indicate that a T-cell mediated inflammatory response was probably the basis of the interaction. When the timing of the infections was altered such that the expulsion of *T. muris* occurred before that of *T. spiralis* there was no reciprocal expulsion of the latter. Mice immunized against one or the other species did not show cross-immunity on heterologous challenge, confirming that the interaction did not involve similar antigens in the two species. The interactive expulsive response is considered to be an example of an indirect cross-immunity.

3871 SMALL INTESTINAL INJURY IN THE GRAFT VERSUS HOST REACTION: AN INNOCENT BYSTANDER PHENOMENON. (Eng.) Elson, C. O.; Reilly, R. W.; Rosenberg, I. H. (Natl. Inst. Health, Bethesda, MD 20014). *Gastroenterology* 72(5):886-889; 1977.

Studies were carried out to determine whether the intestine is injured in the graft-versus-host reaction (GVHR) as an antigenic target of the grafted immunocompetent cells or as an innocent bystander to donor-host lymphoid interaction. Implants of fetal mouse small intestine from either C57BL/6 or (C57BL/6 x DBA/2)F$_1$ (BDF$_1$) hybrid donors were placed under the kidney capsule of adult BDF$_1$ male mice. After 4 weeks, both groups were injected with parental C57BL/6 spleen cells (100 x 10^6 cells, i.v. and 175 x 10^6 cells, i.p.), syngeneic BDF$_1$ spleen cells, or no cells. Two weeks after injection, the mice were killed and the implants were removed. The villus-crypt ratio in the BDF$_1$ implants of mice receiving C57BL/6 cells was 1.32 ± 0.3 compared to 2.51 ± 0.4 in controls receiving either syngeneic BDF$_1$ cells or no cells ($p<0.001$). The villus-crypt ratio in the C57BL/6 implants of mice receiving C57BL/6 cells was 1.79 ± 0.4 compared to 2.48 ± 0.4 in the controls receiving either syngeneic BDF$_1$ cells or no cells ($p<0.001$). Because the latter implant is antigenically identical to the spleen cells eliciting the GVHR, it is concluded that the small bowel is injured in the GVHR as an innocent bystander to cytotoxic donor-host lymphoid interaction.

3872 INTESTINAL LYSOSOMAL ENZYME ACTIVITY IN REGIONAL SIMULATED SHOCK: INFLUENCE OF METHYLPREDNISOLONE AND ALBUMIN. (Eng.) Haglund, U.; Lundholm, K.; Lundgren, O.; Schersten, T. (Surgical-Metabolic Res. Lab., Dept. Surgery II, Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *Circ. Shock* 4:27-34; 1977.

The effects of methylprednisolone (30 mg/kg i.v.) or albumin (intraluminal) on cats subjected to simulated intestinal shock were studied. Methylprednisolone prevented mucosal lesions, cardiovascular deterioration, and release of lysosomal and cytoplasmic enzyme. Albumin deposition prevented lysosomal enzyme release and cardiovascular disturbances, but had only a slight effect on mucosal lesions. The release of intestinal lysosomal enzymes may be important for the development of mucosal lesions and for the production of cardiotoxic material. The effects of methylprednisolone and albumin in preventing damage during shock may be due to the maintenance of microcirculatory integrity.

3873 ANIMAL EXPERIMENTS CONCERNING ESOPHAGOGASTROSTOMY IN ESOPHAGEAL REPLACEMENT OF THE STOMACH. (Ger.) Kunath, U. (Zentrum der Chirurgie der Johann Wolfgang Goethe-Universitat, Theodor-Stern-Kai, D-6000 Frankfurt a. Main, W. Germany). *Langenbecks Arch. Chir.* 343(3):217-227; 1977.

DIAGNOSTIC PROCEDURES

3931 ACCIDENTS IN COURSE OF ESOPHAGO-GASTRODUODENAL FIBROSCOPY. NATIONAL ENQUIRY ON 150,000 ESOPHAGO-GASTRODUODENAL FIBROSCOPIES. (Fre.) Hancy, A.; Condat, M.; Cougard, A.; Mathieu, B.; Pin, G.; Granjon, B.; *et al.* (27, bd d'Athenes, 13001 Marseilles, France). *Ann. Gastroenterol. Hepatol. (Paris)* 13(2):101-110; 1977.

According to a national survey in France, 162 accidents (50 fatal) occurred during a total of 150,680 esophago-gastroduodenal endoscopies. Of the 50 deaths, 31 occurred during emergencies for digestive bleedings and 19 during nonemergency procedures. The major types of accidents included 30 pulmonary injuries (18 fatal due to acute bronchopneumopathy by inhalation); 32, digestive hemorrhaging (13 fatal); 31, digestive perforations (9 fatal); and 12 cardiac accidents (9 fatal). One patient died during operation for esophageal cancer while the endoscope was only at the mouth of the esophagus. Two deaths were attributed to premedication; one of the two patients died after developing ventricular fibrillation subsequent to an injection of atropine. The authors call for caution during these procedures.

3932 RADIOLOGICAL DIAGNOSIS OF CROHN'S DISEASE WITH SPECIAL REFERENCE TO INVOLVEMENT OF THE STOMACH (DOUBLE-CONTRAST METHOD). (Ger.) Habermann, M.; Windorfer, K.; Petzel, H. (Roentgendiagnostische Abteilung der Medizinischen Klinik Bad Cannstatt, Priessnitzweg 24, 7000 Stuttgart 50, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 125(6):508-510; 1976.

Double-contrast radiology was used to diagnose Crohn's disease in a 19-yr-old man. Barium sulfates (70 ml) with dimethylpolysiloxane, followed by 300 ml of air, was given by stomach tube. Initially, the patient had gastric pains, anorexia, vomiting, and anemia. Serum iron was low, and the iron absorption test was pathological. Endoscopy revealed gastric stenosis; duodenal gastric reflux was present, and the entire stomach and bulbus showed mucosal changes indicative of small ulcers with edematous swelling. Histological examination of biopsy material from the bulbus, representative of Crohn's disease, revealed some granulomas that were partially comprised of epitheliallike swollen histiocytes, lymphocytes, and plasma cells. No necroses were seen. Double-contrast radiology showed that the antrum was constricted and that it had a rigid appearance. Contrast medium deposits in the form of irregular fine reliefs were seen. The areae gastricae was partially coarse and vague. The changes extended to the duodenal bulbus. Crohn's disease was detected only in the last 15 cm of the terminal ileum. The large intestine also showed typical Crohn's disease changes, especially in the ascending colon. Crohn's disease of the stomach can be demonstrated by double-contrast radiology through recognition of the detailed mucosal changes, together with other typical findings.

3933 GAS IN PORTAL VEIN OF ADULTS WITH NECROTIZING ENTEROPATHY. (Eng.) Naus, P. J.; Kawanishi, H.; Borlaza, G. S. (Veterans Admin. Hosp., Univ. Michigan Medical Sch., Ann Arbor, MI). *Tex. Med.* 73(3):67-73; 1977.

Case studies of two adult men with severe generalized atherosclerotic vascular diseases and bowel necrosis secondary to mesenteric arterial thrombic occlusion were reported. Gas in the portal vein is a frequent phenomenon that usually indicates intestinal necrosis and demands prompt surgical treatment. The gas is carried to the periphery of the liver by the centrifugal flow of portal radicals. It has been postulated that gas-forming bacteria may cause gas in the portal vein, but there are numerous other associated conditions that may be causal. Air in the hepatic portal vein has frequently been associated with other conditions: peroxide anemia, ingestion of corrosive substances, umbilical vein catheterization, a dead fetus, small bowel obstruction, and rectal bleeding in patients with severe underlying atherosclerotic vascular disease. It has also been reported as a benign phenomenon after barium enema in a patient with ulcerative colitis. In adults, air in the portal vein is predominantly associated with ischemic and bowel necrosis. Shock, sepsis, and instrumentation are predisposing factors. Despite increased observance, few adult survivors with gas in the portal vein have been reported. It was emphasized that a roentgenogram of the right quadrant of the abdomen is needed to establish promptly a correct diagnosis. Since gas in the portal vein is most often the result of enteric necrosis, exploratory celiotomy should be considered immediately. Patients affected with gas in the portal vein do not always appear to be acutely and seriously ill.

3934 HISTOLOGICAL PARAMETERS FOR THE DIAGNOSIS OF HIRSCHSPRUNG'S DISEASE BY DOUBLE SUCTION BIOPSIES. (Ger.) Willital, G. H.; Meier, H. (Chirurgischen Univ.-Klinik, 8520 Erlangen, W. Germany). *Z. Kinderchir. Grenzg.* 21(2):154-167; 1977.

The localization, frequency, and distribution of ganglia and ganglion cells were determined by serial sections of the lowest 6-cm rectal segment of a 4-months-old deceased girl. Results of double variance analyses revealed significant differences in the mean distribution of ganglia cells in the anorectum with respect to the mean distance from the anocutaneous line and the localization of the plexus. Ganglia also showed an irregular distribution pattern in the submucous and myenteric plexus. Examination of the superficial submucous plexus showed significant differences in the ganglia cell density in the first cm proximal to the anocutaneous line as compared with proximal contiguous areas. No significant differences were noted between the 2nd- and 6th-cm segments. The irregular distribution pattern in the submucous and myenteric plexus can result in a false negative result in a suction biopsy, since the ganglion-free areas can exceed the size of the suction in normal individuals. Acetylcholinesterase activity in the lamina propria of the mucosa is more accurately diagnostic of an innervation defect of the intestine as seen in aganglionosis.

3935 RADIOIMMUNOASSAYS OF CEA AND ALPHA-1-ACID GLYCOPROTEIN IN GASTRIC JUICE. APPLICABILITY TO THE DETECTION OF GASTRIC CANCER. (Fre.) Barbotte, P. J.; Bali, J. P.; Remy-Heintz, N.; Balmes, J. L. (Clinique des Maladies de l'Appareil digestif, C.H.R. Saint-Eloi, F 34000 Montpellier, France). *Biol. Gastroenterol. (Paris)* 9(3):233-241; 1976.

Carcinoembryonic antigen (CEA) and alpha-1-acid glycoprotein (AGP) were determined by radioimmunoassays in the gastric juice of patients with gastric cancer (GCa, 28 patients), noncancerous digestive diseases (DD, 30 patients), and 28 controls. GCa was confirmed histologically in 24 patients; 2 had glandular epitheliomas, and 2 had mixed metatypical epitheliomas. Of the 30 DD patients, 15 had benign gastric ulcers (1 with intestinal metaplasia), 9 had a bulbous ulcer, and 6 had hypersecretory or atrophic gastritis. All 58 patients had a significantly elevated AGP level (mean 7,717 and 1,058 μg/ml) compared with the CEA level (mean 2,920 and 668 μg/ml). However, controls had a mean CEA level of 685 μg/ml and a mean AGP level of 276 μg/ml. The total protein level (Lowry method) was slightly raised in the GCa patients. The correlation of AGP and CEA and total proteins was statistically significant. Of the 28 GCa patients, 23 had a positive AGP test, but only 9 had a positive CEA test. Nine of the 30 DD patients also had a positive AGP test, but only 1 showed a positive CEA test. One control subject each had a positive CEA and AGP test. The results suggest that AGP and CEA may be induced by similar mechanisms.

3936 MEASUREMENT OF GASTRIC EMPTYING OF SOLID FOOD. A COMPARISON OF TWO PHASES BY DOUBLE ISOTOPE TECHNIQUE. (Ger.) Guller, R.; Nemec, H. W.; Kyle, L.; Fridrich, R. (Medizinische Universitats-Poliklinik, Hebelstrasse 1, CH-4056 Basel, Switzerland). *Schweiz. Med. Wochenschr.* 107 (13):442-446; 1977.

A method of measuring the rate of gastric emptying of solids using ^{99m}Tc-marked filter paper pieces and ^{198}Au-tagged liver was evaluated in five healthy volunteers. Paper pieces were soaked in ^{99m}Tc sulfur colloid, bathed in 5% plexiglas in chloroform (Perspex), dried, and treated with Perspex again. The liver was obtained from rabbits given ^{198}Au i.v. and killed 0.5 hr later. The rabbit liver was excised and then minced and mixed in equal parts with calf liver. Each subject received about 30 filter paper pieces with an activity of 80 μCi ^{99m}Tc mixed with 200 g potato puree, 70 g of liver with an activity of 50 μCi ^{198}Au, and 200 ml water. In all five subjects, the pieces of filter paper were emptied from the stomach at a significantly faster rate ($p<0.05$) than from the liver; a linear emptying pattern was demonstrated in each instance. The difference in the rate of emptying of both solid phases differed in each subject. The results indicate that both solids and liquids and different types of solids are emptied from the stomach at different rates. The use of ^{99m}Tc-labeled filter paper is a justified and practical method for measuring gastric emptying of solid food.

3937 INFLUENCE OF AMYLASE ASSAY TECHNIQUE ON RENAL CLEARANCE OF AMYLASE-CREATININE RATIO. (Eng.) Levitt, M. D.; Johnson, S. G.; Ellis, C. J.; Engel, R. R. (Box 346, Dept. Medicine, Univ. Minnesota, Minneapolis, MN 55455). *Gastroenterology* 72(6):1260-1263; 1977.

The influence of amylase assay technique on the renal amylase/creatinine clearance (Cam/Ccr) measurement was determined by analyzing serum and urine specimens obtained from 10 normal subjects. Cam/Ccr averaged 2.19 ± 0.18% with a saccharogenic technique, 1.52 ± 0.2% with an iodometric technique, and 0.80 ± 0.08% with a chromogenic technique. Each of these values differed significantly ($p<0.05$) from the other two. Recovery studies were carried out by adding partially purified human salivary or pancreatic amylase to human newborn serum or urine (which contain minimal endogenous amylase). Equal amylase activity was recovered from serum and urine by the saccharogenic technique, whereas recovery from urine was less than 50% of that from serum using the iodometric and chromogenic techniques. The accuracy of the chromogenic technique was markedly improved by the addition of albumin to the urine assay system. Although it appears that only the saccharogenic method provides an accurate estimate of Cam/Ccr, each assay technique distinguished the elevated Cam/Ccr of patients with pancreatitis from the normal range established for that technique. Accurate clinical interpretation of Cam/Ccr measurement requires knowledge of the amylase assay technique used.

3938 PANCREATIC FUNCTIONAL EXPLORATION BY DUODENAL TUBAGE AFTER CERULEIN AND SECRETIN STIMULATION. (Fre.) Gislon, J.; Lefevre, R.; Fiesse-Vandale, P. Y.; Bonfils, S. (Service de Gastro-Enterologie B, Hopital Bichat, 170, boulevard Ney, F 75877 Paris Cedex 18, France). *Arch. Fr. Mal. App. Dig.* 65(6):463-472; 1976.

The effect of a single injection of cerulein (30 ng/kg) on amylase, lipase, and bicarbonate secretion during secretin perfusion (2 Boots U/kg/hr) was studied in 68 subjects: 25 patients with chronic pancreatic disease, 23 with various digestive diseases, and 20 normal controls. Patients with chronic pancreatic disease had much lower bicarbonate and amylase concentrations. Patients with various digestive disorders showed random fluctuation in these parameters. The authors suggest that the method may be useful for detecting pancreatic deficiencies in early stages.

3939 POSSIBILITIES AND LIMITATIONS OF ANGIOGRAPHY FOR CHRONIC PANCREATITIS. (Fre.) Magotteaux, P.; Delvigne, J. (Hopital de Baviere, Boulevard de la Constitution 66, B-4000 Liege, Belgium). *Acta Gastroenterol. Belg.* 39(11/12):490-501; 1976.

The advantages and disadvantages of angiography (AR) in the diagnosis of chronic pancreatitis is reviewed. Selective catheterization, according to the method of Seldinger, allows visualization of arteries, capillaries, parenchyma, and veins. Superselective catheterization yields an image of the lesion itself. If this fails, vasoconstrictors (adrenalin and nonadrenalin derivatives) or vasodilators are injected. AR allows a direct view of pancreatic structures so that small lesions, and the nature of the lesions, may be elucidated. It also yields precise information on neighboring organs (liver, spleen, and vesiculae), giving a complete evaluation of possible lesions of the upper abdomen. However, AR has certain disadvantages. It is sometimes difficult to establish a differential diagnosis between malignant tumor of the pancreas and chronic pancreatitis, when the tumor is relatively small. A 2% complication rate was noted in 2,000 abdominal examinations by AR, which included thrombosis (3) of the femoral artery at the site of puncture. Acute and irreversible mesenteric ischemia developed after catheterization of the superior mesenteric artery in an elderly patient with severe arteritis. Through its direct approach, arteriography enables the detection of very small pancreatic lesions; however, its use should be limited as it is an aggressive technique, which requires specialized tools.

3940 ABDOMINAL TOMOMETRY. APPLICATION TO STUDY OF THE LIVER. EXPERIMENTAL STUDY, INITIAL CLINICAL RESULTS AND PERSPECTIVES IN THE EXPLORATION OF TUMOR PATHOLOGY.

(Fre.) Lamarque, J. L.; Bruel, J. M.; Dondelinger, R.; Senac, J. P.; Rabischong, P.; Bonnel, F.; *et al.* (Hopital Saint-Eloi, F 34000 Montpellier, France). *J. Radiol. Electrol. Med. Nucl.* 58(4):253-260; 1977.

An Acta-Scanner tomometer was used to study various hepatic disorders in 120 patients, and comparative tomometric and pathological studies were carried out on cadavers and isolated livers. Serial axial transverse sections allowed for the reconstruction of the actual volume of liver. Densitometry led to a quantified diagnosis of certain diffuse hepatic diseases and a histological approach to tumor lesions. Fifty-six patients had livers with normal morphology and 64 presented with pathologic livers. Twenty tumor lesions observed included benign hydatid cysts, hamartomas, calcified hemangiomas, malignant hepatomas, and hepatic metastases. The nontumorous lesions included dilatations of the intrahepatic biliary tract, hepatic trauma, and amebic abscess. Histological examination showed that, in the majority of the cases, the tumor lesions absorbed less iodized opacifier than healthy parenchyma; the morphological picture was that of an intrahepatic defect. Cysts and the abscess appeared as homogeneous hypodense zones. Nontumor lesions appeared as rounded or elongated defects. Of the 20 cases described, only 3 false negatives occurred. Clinically, after i.a. or i.v. injection of liposoluble agents, lesions >1 cm in diameter could be easily recognized or localized. Hepatography with low doses of liposoluble agents (0.04 ml/kg) in pigs showed that the 2-6 mm defects induced with a probe became clearly visible regardless of the hepatic topography. The Acta-Scanner tomometer for various hepatic disorders made possible the recognition of normal structures and the identification of certain hepatic images that may be potential sources of error. This method allows hepatosplenic tumors <1 cm in diameter to de diagnosed.

3941 NEW THERAPEUTIC POSSIBILITIES IN THE DIAGNOSIS OF CONGENITAL CYSTIC BILE DUCT DILATATIONS.

(Ger.) Faust, H.; Gyr, K. (Institut fur Medizinische Radiologie, Universitat Basel, CH-4004 Basel, Switzerland). *Fortschr. Roentgenstr.* 126(3):209-212; 1977.

A 30-yr-old woman, suspected of having recurrent pancreatitis and sclerosis of Vater's papilla, was examined by cholecystography and i.v. cholangiocystography. No pathology was found; however, retrograde cholangiocystography revealed enlarged bile and hepatic ducts, with multiple polygonal, prepapillary, pinhead-sized concretions of contrast medium and enlarged bile ducts with multiple cystic sacs in the liver. The cystic duct and the gallbladder showed no abnormalities. These findings are characteristic of congenital bile duct dilatation described by Caroli. Following intraoperative cholangioscopy, choledochotomy was performed with bile duct revision, transduodenal papillotomy, cholecystectomy, and T-drainage. Irrigation with chenodeoxycholic acid with prophylactic antibiotics was carried out and the intrahepatic concretions were diminished. The value and risks of prophylactic p.o. therapy with chenodeoxycholic acid after removal of T-drain have not been determined.

3942 DOUBLE-STRANDED DNA-BINDING CAPACITY OF SERUM IN ACUTE AND CHRONIC LIVER DISEASE.

(Eng.) Jain, S.; Markham, R.; Thomas, H. C.; Sherlock, S. (Royal Free Hosp., Pond St., London NW3 2QG, England). *Clin. Exp. Immunol.* 26(1):35-41; 1976.

Serum antibodies to double-stranded native DNA were measured in patients with acute and chronic liver diseases using the Farr technique. Elevated DNA binding levels were found in all groups of patients when compared with the mean value of 25 ± 3.1% for 27 healthy subjects. The mean DNA binding levels for 27 patients with systemic lupus erythematosis, 59 patients with hepatitis B surface antigen (HBsAg)-negative chronic active hepatitis (CAH), 15 patients with HBsAg-positive CAH, 38 patients with primary biliary cirrhosis, 16 patients with alcoholic cirrhosis, 15 patients with acute type A hepatitis, and 12 patients with acute type B hepatitis were 51 ± 15.0, 41.1 ± 16.0, 41.9 ± 5.8, 28.8 ± 8.5, 37.6 ± 8.7, 50.7 ± 9.6, and 46.8 ± 6.9%, resp. Within each diagnostic group, the correlation between DNA binding and serum aspartate transaminase (AsT) levels was highly variable, suggesting that elevated DNA binding is not a simple reflection of hepatocellular damage. The AsT level, which was initially 368.5 ± 361.1 IU/l for acute type A viral hepatitis and 588.3 ± 283.3 IU/l for acute type B, fell toward normal faster than did DNA binding as these patients recovered, with the recovering AsT levels being 38.3

± 52.6 and 34.6 ± 36.2 IU/1 for types A and B hepatitis, resp., and the recovering DNA binding levels being 40.3 ± 8.6 and 35.0 ± 9.0% for types A and B hepatitis, resp. In all of these patients, the outcome was clinical and biochemical recovery, and those who were HBsAg-positive eventually became negative. However, all of the patients with HBsAg-positive CAH had elevated DNA binding, suggesting that continued elevation might be an unfavorable prognostic marker in acute type B hepatitis. DNA antibody levels will not offer diagnostic help in chronic liver diseases, and because DNA binding was elevated in HBsAg-negative CAH patients who were either biochemically controlled or uncontrolled by corticosteroid therapy, it will not help in assessing which of these patients responds favorably to steroid treatment.

3943 EVALUATION OF BILIARY TRACT DISEASE BY ULTRASONIC B-MODE SCANNING. (Eng.) Addison, N. V.; Follows, O. J.; Weedon, M. R. (Royal Infirmary, Bradford, England). *Br. J. Surg.* 63(10): 784-787; 1976.

The place of the sonar scan in the diagnosis of biliary tract disease was evaluated, and the information obtained by this method was compared with information obtained from plain films, contrast radiography, and laparotomy. One hundred and forty patients with symptoms of biliary colic, acute and chronic cholecystitis, acute pancreatitis, and jaundice were scanned and also had a plain film of the biliary tract; 105 also had p.o. cholecystography or i.v. cholangiography, and 123 underwent laparotomy. Among the 133 patients who had not undergone a previous cholecystectomy, ultrasonic B-mode scanning visualized the gallbladder in 119. The scan indicated the presence of gallstones in 55 cases; 47 were confirmed at laparotomy, and 8 were false positives. There were 25 false negative cases. Among these 25, stones had been diagnosed by p.o. radiography in 10 cases and by i.v. radiography in 2 others. The common bile duct was not visualized by the scan in 13 cases. The gallbladder was visualized by the sonar scan in 19 of 24 patients with transient jaundice. The scan detected stones in 11 of 17 patients with stones detected at laparotomy, whereas stones were seen with contrast radiography in 12 cases (70%). The results suggest that, in the absence of jaundice, sonar compares well with p.o. cholecystography in demonstrating the gallbladder, but is not as useful as i.v. cholangiography in demonstrating the duct system. In the presence of jaundice, sonar is the imaging examination of choice.

3944 CLINICAL EVALUATION OF ^{99m}Tc-PYRIDOXYLIDENEGLUTAMATE FOR HEPATOBILIARY SCANNING. (Eng.) Matolo, N. M.; Stadalnik, R. C.; Wolfman, E. F., Jr. (Univ. California Sch. Medicine, Davis, CA 95616). *Am. J. Surg.* 132(6):716-719; 1976.

The use of technetium 99m-pyridoxylideneglutamate (^{99m}Tc-PG) in hepatobiliary scanning was evaluated clinically in 20 normal volunteers and 83 patients with hepatobiliary tract disease. Sequential images were obtained at 5, 10, 20, 30, and 60 min after the i.v. injection of ^{99m}Tc-PG (2-3 mCi or, in jaundiced patients, 4-5 mCi). These concentrations allowed satisfactory imaging of the biliary ductal system and the gallbladder. In normal subjects, the agent reached the liver in 5 min, and the common bile duct, gallbladder, and duodenum in 10-20 min. In the seven patients with partial common bile duct obstruction, a distended duct was visualized, and there was a delay in transit of radioactivity into the duodenum. The gallbladder was not visualized when the cystic duct was obstructed in patients with acute and chronic cholecystitis. In the 13 patients with complete common bile duct obstruction, no radioactivity was seen in the biliary or gastrointestinal tracts up to 24 hr after injection. In all 22 patients with hepatocellular disease, delayed liver clearance and delayed visualization of the biliary and gastrointestinal tracts were observed. No toxic or other untoward effects were noted in any patient. ^{99m}Tc-PG cholescintigraphy is a simple and safe diagnostic modality for the initial evaluation of patients with acute cholecystitis or jaundice.

3945 HEPATOBILIARY SCANNING USING ^{99m}Tc-PYRIDOXYLIDENEGLUTAMATE. (Eng.) Matolo, N. M.; Stadalnik, R. C.; Wolfman, E. F., Jr. (Univ. California Sch. Medicine, Davis, CA 95616). *Am. J. Surg.* 133(1):116-120; 1977.

Clinical experience is reported with technetium 99m-pyridoxylideneglutamate (^{99m}Tc-PG) cholescintigraphy in 27 normal volunteers, 84 patients with right upper quadrant pain, and 55 patients with jaundice. Patients without jaundice received 2-3 mCi of ^{99m}Tc-PG i.v., and jaundiced patients received 4-5 mCi. ^{99m}Tc-PG was not associated with any toxic or other untoward effects, and satisfactory images of the biliary tract were obtained with the doses used. Radioactivity in the normal volunteers appeared in the common bile duct, gallbladder, and duodenum within 15 min. The gallbladder was not visualized when the cystic duct was occluded. Among the 84 patients with pain, 46 had acute or chronic cholecystitis. These patients all had nonvisualization of the gallbladder, but the hepatic duct, common bile duct, and duodenum were visualized in all cases. Each was proved operatively and histologically to have acute and/or chronic cholecystitis with cystic duct obstruction. Of the 55 jaundiced patients, 8 had partial common bile duct obstruction, and all had prompt visualization of the biliary tract with a distended common bile duct but delayed ^{99m}Tc-PG secretion into the duodenum. In 16 patients with complete extrahepatic biliary obstruction, no concentration of the agent was seen in the biliary and gastrointestinal tracts up to 24 hr after injection. Delayed visualization of the biliary and gastrointestinal tracts was seen in the 31 jaundiced patients with hepatocellular disease. ^{99m}Tc-PG cholescintigraphy is valuable in the initial evaluation of patients with acute cholecystitis or jaundice. Other advantages include safety, simplicity, and availability.

3946 SPLENIC ^{198}Au UPTAKE DURING SCINTIGRAPHY FOR HEPATOMA. (Ita.) Roncaia, R.; Piaggi, V. (Istituto di Clinica Medica, Universita di

Modena, Modena, Italy). *Prog. Med. (Roma)* 31(6): 268-273; 1975.

The diagnostic value of ^{198}Au splenic uptake in the detection of primary hepatoma was studied retrospectively in 849 case histories of patients with liver cirrhosis (808), primary hepatoma without cirrhosis (14), and cancer-induced cirrhosis (27). All patients were subjected to routine hepatic scintiscanning with ^{198}Au. ^{198}Au splenic uptake was found in all 41 cirrhotic patients (other results not reported); uptake was associated with medullary fixation of the isotope in 8 of these patients, and was interpreted as a definite absence of hepatoma. Among the patients with cancer-induced cirrhosis confirmed by positive biopsies and the presence of fetoprotein, 25 showed splenic uptake, which was associated with medullary fixation in 10. No splenic uptake was seen in the patients with confirmed primary hepatoma. The absence of splenic ^{198}Au uptake after hepatic scintiscanning appears to be a valid test for the detection of primary hepatoma. ^{198}Au splenic uptake found in rare cases of apparently primary hepatoma may be due to portal hypertension, modifications of the hepatosplenic flow, and reticuloendothelial activation leading to a cirrhogenous process. The correct diagnosis in such cases should be that of cancer-induced cirrhosis.

3947 SERUM LIPASE ACTIVITY AND EVOCATION TESTS AFTER ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY.

(Ger.) Kratochvil, P.; Brandstatter, G.; Wiedner, F.; Justich, E.; Petek, W. (Landeskrankenhaus Graz, Auenbruggerplatz 1, A-8020 Graz, Austria). *Wien. Klin. Wochenschr.* 89(7):227-231; 1977.

Serum lipase activity (SLA) was determined in 51 patients before, immediately after, and 24 hr after endoscopic retrograde cholangiopancreatography (ERCP). A lipase evocation test was performed in 10 of the patients with elevated SLA 2-10 days after ERCP to determine the extent of tissue damage. An increase in SLA without clinical signs of acute pancreatitis was noted immediately after the procedure in 20/51 patients; 24 hr later SLA was still high in 3 of these patients, rising in 2, normal in 11, and diminished in 4 patients. The behavior of SLA in patients with pathological duct changes did not differ from patients with a normal pancreatogram. The extent of a rise in SLA after ERCP is not dependent upon pathological duct changes but upon the extent of retrograde duct filling. The lipase evocation test performed 10 days after ERCP showed negative results in patients with increased SLA and parenchymography. However, positive pathological results were noted 2 days after ERCP in four patients. Injection of contrast medium into the pancreatic duct may cause a reversible damage of the pancreas by increasing membrane permeability of the acinous cells. A series of 150 tests showed that the addition of gentamycin (40 mg to 20 ml 60% urografin) to the contrast medium may prevent the development of acute pancreatitis: three cases of pancreatitis developed in a series of 200 tests in which gentamycin was not injected with urografin.

3948 ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY IN THE DIAGNOSIS OF BILIARY TRACT CARCINOMA: A STUDY OF 23 CASES.

(Fre.) Bitoun, A.; Bognel, J. C.; Bernier, J. J. (Clinique Gastro-Enterologique, Hopital Saint-Lazare, 107, rue du Faubourg-Saint-Denis, F 75010 Paris, France). *Arch. Fr. Mal. App. Dig.* 65(5):361-367; 1976.

Biliary tract carcinoma was diagnosed in 23/276 patients with cholestatic jaundice by endoscopic retrograde cholangiography (ERC). Patients were medicated with droperidol and phenoperidine. The contrast agent methylglycamide was mixed with gentamycin and injected into the biliary tract. The tumor was localized in the porta hepatica (PH) in nine patients, common bile duct (CBD) in eight, and gallbladder (GB) in six patients. Laparoscopy of 9/23 patients revealed an enlarged cholestatic liver in all 9. The GB was normal or flat in five of these patients, and one appeared to bear a neoplasm. The nine tumors localized in the PH appeared irregular and stenotic, with infiltrations to the GB. All patients had their tumor excised. Of the eight patients with CBD tumors, four had cancer of the intrapancreatic bile duct with stenosis, and the other four had cancer of the hepatic bile duct. Of the six patients with suspected GB tumors, one had lithiasis of the CBD. Upon surgery, retropancreatic ganglionic metastases were found in 1/23 patients. Following ERC, cholangitis with septicemia developed in one patient with GB cancer. She was cured after a surgical shunt procedure was performed 48 hr after catheterization.

3949 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY WITH THE "SKINNY" NEEDLE: A RAPID, SIMPLE AND ACCURATE METHOD IN THE DIAGNOSIS OF CHOLESTASIS.

(Eng.) Pereiras, R.; Chiprut, R. O.; Greenwald, R. A.; Schiff, E. R. (Veterans Admin. Hosp., 1201 N.W. 16th St., Miami, FL 33125). *Ann. Intern. Med.* 86: 562-568; 1977.

Radiographic findings with "skinny" needle cholangiography in 129/131 patients with cholestasis were confirmed in subsequent surgery or autopsy. Biliary trees were successfully visualized in all 86 patients with dilated biliary ducts, and this method was useful in diagnosing various disorders: (1) bifurcation tumors and high biliary tract disease; (2) common duct stones; (3) pancreatic disease, especially in the presence of active inflammatory process; and (4) when previous surgery had altered gastrointestinal tract so that retrograde visualization was not possible. The "skinny" needle technique successfully visualized the biliary tree in 43/45 patients with nondilated ducts and varied pathology: (1) cirrhosis, with or without extrahepatic obstruction; (2) benign postoperative cholestasis; and (3) sclerosing cholangitis. Six cases are presented in detail, and technical recommendations on the procedure are given.

3950 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY.

(Cze.) Fric, P.; Horacek, F.; Kotrlik, J.; Ronsky, R.; Vondrackova, M.; Pitha, F.

(II. vedecke gastroenterologicke oddeleni fakulty vseobecneho lekarstvi University Karlovy, 121 11 Prague 2, Karlovo nam. 32, Czechoslovakia). *Cas. Lek. Cesk.* 115(37):1135-1141; 1976.

GASTROINTESTINAL DISEASES

ESOPHAGUS

4019 ENDOSCOPIC AND HISTOLOGICAL CHANGES AT THE Z-LINE. (Ger.) Clemencon, G.; Gloor, F. (Kantonsspital Olten, Frohheinweg 12, CH-4600 Olten, Switzerland). *Dtsch. Med. Wochenschr.* 102(16): 609-612; 1977.

Endoscopic and histological changes of the Z-line were studied in 79 patients (23 women and 56 men, mean age of 47.5 yr) with reflux esophagitis. Selective forceps biopsies were obtained from the Z-line, from the cardia directly beneath it and from the esophagus 1-3 cm above. Of the 79 patients, endoscopy was normal in 47, and 30 showed grade I changes (lymphocytes, plasma cells in superficial mucosal layers); 2 patients presented with grade II changes (superficial gastritis). Histological examination of 72 patients showed that 24 had no inflammatory changes of the Z-line, whereas 31 had grade II and 17 had grade III changes. Of 70 patients evaluated for changes of cardiac mucosa, 47 showed no inflammation, while 16 had grade II and 7 had grade III inflammatory changes. Esophageal mucosa was not changed in 58 patients, whereas marked inflammatory cell infiltration was seen in 13 patients. A comparison of endoscopy and histology findings showed that when grade III changes are taken into consideration, only 6/43 patients with normal endoscopy presented inflammation in comparison with the inflammation observed in 11/28 with pathological endoscopic findings. Thus, endoscopy with histological examination can reveal reflux esophagitis in the early stages, but the differentiation from normal remains difficult.

4020 ACHALASIA OF THE ESOPHAGUS: CORRELATION OF CLINICAL, RADIOLOGICAL, AND MANOMETRIC FINDINGS. (Fre.) Couturier, D.; Roze, C.; Rosemond, A.; Guindo, A.; Lequerler, Y.; Debray, C. (Hopital Bichat, 170, boulevard Ney, F 75877, Paris Cedex 18, France). *Gastroenterol. Clin. Biol.* 1: 151-157; 1977.

Achalasia of the esophagus was diagnosed by clinical, radiological, and manometric findings in 43 patients (13-82 yr of age). Of the 43 patients, 34 were treated by pneumatic dilations. Manometry showed that basal pressures in the lower sphincter, the esophagus, and the upper sphincter were significantly stronger in 43 patients with achalasia as compared to 10 healthy controls. On the average, 4.6 yr elapsed from the onset of the first symptoms to time of diagnosis; 12/43 patients presented with esophageal pain. Radiology revealed definite distension of the esophagus: a median value of 4.1 cm for the entire group as compared with normal dimension of no more than 3 cm. Regurgitation was present in 24 of the patients before (16) or after (8) meals; late regurgitation was present in most of the patients with large extension of the esophagus. Notches at the edges of the esophagus suggesting tertiary contractions were observed in 30% of the cases. The diagnosis of achalasia of the esophagus was made by manometry in 18% of the patients who did not have distension of the esophagus. A very satisfactory improvement in symptoms occurred in 56% of the patients following pneumatic dilations.

4021 RADIOTHERAPY OF ESOPHAGEAL CANCER. A REVIEW OF 136 CASES TREATED AT THE BORDET INSTITUTE. (Fre.) Van Houtte, P. (Institut Jules Bordet, Rue Heger-Bordet 1, B-1000 Brussels, Belgium). *Acta Gastroenterol. Belg.* 40(3/4):121-128; 1977.

The results of treatment of 136 patients with esophageal cancer by high-energy radiotherapy (5,000-8,000 rads in 6 weeks), alone (120 patients), or in addition to surgery (16) are presented. The ages of the patients ranged from 34 to 94 yr; 75% were older than 60 yr, and the ratio of men to women was 5 to 1. A histological diagnosis was obtained by esophagoscopy in 103 cases: malpighian carcinomas (97), adenocarcinomas (5), and leiomyosarcoma (1); no histological data were available in 33 cases, all of whom eventually died of their neoplasia. Of the 120 patients given only radiotherapy, 26 survived 1 yr; 7, 2 yr; 2, 3 yr; 1 patient died after 7 yr; and 1 was still alive at 4 yr. Overall, two-thirds of the patients had transient radiological or clinical evidence of improvement. The dose of radiation did not affect the treatment results. Of the 16 patients given combination therapy, only 1 patient survived 5 yr, whereas the others died within a year of tumor evaluation. Complications of radiation treatment included perforations (13), partial myelitis (1), and death due to bronchopneumonia from regurgitation subsequent to esophageal stenosis without signs of local recurrence or generalization. Twenty-six histological controls obtained by esophagoscopy after radiotherapy demonstrated local sterilization of tumor.

4022 THE ASSESSMENT OF OPERABILITY OF ESOPHAGEAL CARCINOMA. (Eng.) Murray, G. F.; Wilcox, B. R.; Starek, P. J. K. (Univ. North Carolina Sch. Medicine, Clinical Sciences Building 229H, Chapel Hill, NC 27514). *Ann. Thorac. Surg.* 23(5):393-399; 1977.

The effectiveness of combined mediastinoscopy and celiotomy for assessing the operability of esophageal epidermoid cancer was evaluated in 30 patients (23 men, 7 women) with esophageal carcinoma. Mediastinoscopy revealed cancer in only 5/18 patients with upper thoracic and midthoracic esophageal carcinoma and in 0/12 patients with lower thoracic esophageal carcinoma. Survival in the five patients with positive mediastinoscopy was brief. Exploratory laparotomy of celiac lymph nodes revealed celiac metastasis in 16/26 patients. All of these 16 patients survived <1 yr, due to extension of cancer outside of the esophagus. Curative resection was possible on 7/10 patients with negative mediastinoscopy and negative celiotomy. Of these seven patients, four survived 14-30 months or more following resection.

Prognosis is very poor for patients with positive mediastinoscopy or celiotomy, and surgical resection did not prolong their survival.

4023 ESOPHAGEAL TUBERCULOSIS PRESENTING AS MASSIVE HEMORRHAGE.

(Fre.) Roche, J. Y.; Desfemmes, F.; Coffin, J. C.; Callard, P.; Patel, J. C. (No affiliation given). *Chirurgie* 103(3):177-182; 1977.

A fatal case of persistent hemorrhaging esophageal tuberculosis complicated by an esophageal ulcer is reported in a 20-yr-old man. Initially, the patient presented with bleeding and endoscopy revealed gastritis that was attributed to recently ingested aspirin. Repeated hemorrhaging required emergency laparotomy and a Blakemore tube was inserted to stop the bleeding. Esophagoscopy showed nonbleeding esophageal ulcers but signs of massive bleeding were seen in the throat. The closing of the esophagotomy was very difficult; hemostasis was obtained by insertion of a Blakemore tube followed by blood infusion, antituberculostatics, and corticoid therapy. Analysis of a tissue sample confirmed tuberculosis. The patient became apyretic in 3 days and stopped bleeding. However, septicemia, collapse, and minor hemorrhaging (hematocrit 28%) occurred on the 6th, 9th, and 11th postoperative day, and the patient died of a massive irreversible hemorrhage on the 15th day. Numerous caseo-follicular tuberculous ganglions were found at the superior posterior surface of the thoracic esophagus and there were three lesions of the esophageal mucosa; two of the lesions were diverticula opposite tuberculous ganglions and the third was a tuberculous ulceration that had destroyed the musculature and eroded an artery. The patient had chronic hepatitis and tiny periportal caseo-follicular lesions. No tuberculous foci of the pulmonary parenchyma were seen.

4024 DETECTION AND GRADING OF OESOPHAGEAL VARICES BY FIBRE-OPTIC ENDOSCOPY AND BARIUM SWALLOW WITH AND WITHOUT BUSCOPAN.

(Eng.) Waldram, R.; Nunnerley, H.; Davis, M.; Laws, J. W.; Williams, R. (King's Coll. Hosp., London SE5, England). *Clin. Radiol.* 28(2):137-141; 1977.

The results of fiberoptic endoscopy in the detection and grading of esophageal varices were compared with those of barium swallow (with and without hyoscine *N*-butyl bromide) in 56 patients with chronic liver disease. Esophageal varices were graded as small, moderate, or gross by independent observers for each technique. In 12 patients, varices were not detected by either method, and in 6 cases, varices were detected by endoscopy when the barium swallow was negative. In 15 of the remaining 38 patients, varices were found to be one grade larger at endoscopy than on barium swallow. Because of the possibility that varices appear larger at endoscopy due to the hyoscine *N*-butyl bromide used as a relaxant, barium examinations were carried out after the administration of the drug (20 mg, i.v.) in 23 patients. In eight cases, varices were one grade larger after the administration of the relaxant than on the standard barium swallow, and in two were only detected after it had been given. Eight cases negative after hyoscine *N*-butyl bromide were also negative at endoscopy. Although emergency endoscopy has particular value in locating the site of bleeding in patients with portal hypertension and acute gastrointestinal hemorrhage, the results suggest that a barium meal with hyoscine *N*-butyl bromide is as accurate as endoscopy in the detection of esophageal varices.

4025 SCLEROSING THERAPY OF ESOPHAGEAL VARICOSIS.

(Ger.) Denck, H.; Sponer, D. (I. Chirurgische Abteilung des Krankenhauses der Stadt Wien-Lainz, Wolkersbergenstrasse 1, A-1130, Vienna, Austria). *Langenbecks Arch. Chir.* 342:173-179; 1976.

The results of sclerosing therapy with Dondren of esophageal varicosis in 422 patients are presented. The agent is composed of granugenol (0.2 g), benzyl alcohol (0.006 g), terpentine oil (0.004 g), diacetylaminoazotoluene (0.02 mg), and liquid paraffin. Between 4 and 20 ml were used at each sitting. The submucosa became sclerotic after the formation of inflammatory edema, from which fibrous scar tissue develops. Of the 422 patients, 51 died of recurrence of bleeding after 0-17 yr. Mortality after sclerosing therapy (12%) was lower than that after emergency shunt operations (29%). Esophagoscopy of 1,280 patients at one clinic revealed that most cases of bleeding were caused by esophageal varicosis (527), duodenal ulcer (271), and peptic ulcer (207).

STOMACH

4038 CURRENT ANGIOGRAPHIC APPROACH TO DIAGNOSIS AND THERAPY OF ACUTE GASTROINTESTINAL BLEEDING. (Eng.) Rosch, J.; Antonovic, R.; Dotter, C. T. (Univ. Oregon Health Sciences Center, Sch. Medicine, Portland, OR 97201). *Fortschr. Geb. Roengenstr. Nuklearmed.* 125(4):301-310; 1976.

An angiographic approach to the diagnosis and therapy of acute gastrointestinal bleeding is discussed. More than 300 acute gastrointestinal bleeders were studied, and angiotherapeutic techniques were used on 138 of them. A moderately aggressive angiographic approach is advocated for diagnostic purposes, because angiography could give nonproductive results and endanger patients. Emergency endoscopy is suggested as the first procedure of choice, because it indicates the site of and directly exposes the lesion. Medical therapy or surgery is suggested next, depending on the patient's condition. Vasoconstrictive angiotherapy with selective intra-arterial use of vasopressin is reported to be partially replaced by low dose, i.v. infusion of vasopressin (0.2-0.3 U/min). Acute variceal bleeding was stopped in 22 of 28 patients by this technique. Direct vascular occlusion of the bleeding artery is reported to be a useful therapeutic method in managing gastrointestinal bleeding, particularly where vasoconstriction has failed. Selective transcatheterembolic occlusion of bleeding vessels with medical gelatin is suggested for controlling arterial bleeding. A selective variceal occlusion might provide promising means for management of bleeding from gastroesophageal varices. It is possible that combination of this method with transcatheter intrahepatic portosystemic shunting might provide nonsurgical relief of portal hypertension.

4039 EARLY GASTRIC CARCINOMA. 20 CASES. RADIO-CLINICAL, ENDOSCOPIC AND HISTOPATHOLOGICAL STUDY. (Fre.) Negrin-Fragoas, M.; Taieb, A. (17, rue du repos, 75020 Paris, France). *J. Radiol. Electrol. Med. Nucl.* 58(4):269-278; 1977.

Early gastric carcinoma (GC) was studied in 20 patients (11 men, 9 women; age 45-74 yr, median age, 58 yr) by radiology, endoscopy, or histopathology. Symptoms of early GC included typical ulcer syndrome (10 times), atypical epigastric pain or dyspepsia (4), corticoid therapy-induced epigastralgia (1), and digestive hemorrhaging (7). Of the 20 patients, 17 had stage I and II and 3 had stage III carcinomas. Endoscopy revealed projecting, ulcerated, or flat lesions. The former type presented as a filling defect or appeared as large-based polyps, whereas the ulcerated type appeared either as isolated or deep, regressive ulcerations. The flat forms caused an abnormal, smooth, or rounded mucous zone. Anatomically, these lesions were polymorphic and varied widely. Radiologically, the projecting lesions did not suggest cancer, and only histology was able to confirm malignancy. The other forms appeared as superficial or benign ulcers with nodular or widespread folds. Overall, endoscopic results were evaluated as characteristic (3 times), doubtful (6), and benign (2). The differential diagnosis of early GC is difficult because the clinical signs are not alarming, and radiological images are difficult to interpret.

4040 TRANSPYLORIC PROLAPSE OF POLYPOID GASTRIC CARCINOMA. (Eng.) Joffe, N.; Goldman, H.; Antonioli, D. A. (Beth Israel Hosp., 330 Brookline Ave., Boston, MA 02215). *Gastroenterology* 76(2):1326-1330; 1977.

Four patients with discrete intraluminal filling defects in the duodenal bulb secondary to transpyloric prolapse of polypoid gastric carcinoma are discussed. The patients ranged in age from 59 to 79 yr. In two patients, there were no specific abdominal complaints; in both, discovery of the lesion resulted from a work-up for hypochromic anemia and guaiac-positive stools. In one patient, malignancy was suspected because of epigastric pain, anorexia, weakness, and weight loss. In the remaining patient, recurrent episodes of epigastric pain and vomiting raised the possibility of gastric outlet obstruction. Apart from guaiac-positive stools and anemia, which were present in three patients, the clinical examination and laboratory data were normal. An upper gastrointestinal series revealed the intraluminal filling defect in the duodenal bulb in all patients and a similar but smaller defect in the prepyloric region of the antrum in one patient. The malignant nature of the lesions was established preoperatively by endoscopy and biopsy in two patients and at operation in the other two. Two tumors were pedunculated and two were sessile. The lesions were composed entirely of carcinoma in three cases and, in one, carcinoma appeared to arise in a preexisting adenoma. The carcinoma was limited to the mucosa in all patients, and there was no evidence of metastasis. Prolapsed gastric carcinoma should be included in the differential diagnosis of localized intraluminal filling defects in the duodenal bulb.

4041 ENDOSCOPIC STUDY OF GASTRIC LYMPHOMAS. (Fre.) Gruselle, P.; Mainguet, P.; Haot, J.; Willock, R.; Dive, Ch. (Service de Gastroenterologie, Cliniques Universitaires Saint-Pierre, Louvain, Belgium). *Acta. Gastroenterol. Belg.* 39(9/10): 358-365; 1976.

Ten patients with gastric lymphomas were studied by fibergastroscopy and multiple systematic biopsies (128 total). All patients had multiple lesions with one or several giant ulcerations. The lesions were mostly found in the small vertical curvature and antrum and subcardially. The giant ulcerations in 8/10 patients were associated with submucosal, multiple, ulcerated, and nonulcerated nodules. Large permanent folds, small ulcerated tumors, and erosions were seen in five patients. Eight of the 10 patients were suspected of having lymphoma according to endoscopic images and gastric biopsies. Final histological diagnosis revealed mixed or lymphocytic lymphoma in eight patients, histiocytic lymphoma in one, and Hodgkin's disease in one.

4042 DIAGNOSIS OF MULTIPLE GASTRIC CARCINOID TUMORS IN GASTRIC POLYPOSIS. (Ger.) Langhans, P.; Clemens, M.; Schonleben, K.; Heger, R. A.; Schlake, W. (Chirurgische Klinik und Poliklinik der Univ. Allgemeinchirurgie, 4400 Munster/Westfalen, W. Germany). *Roentgenblaetter* 30(3):133-138; 1977.

The problems in the diagnosis and treatment of multiple gastric carcinoid tumors in a patient are presented. X-ray examination revealed multiple filling defects as seen in polyposis ventriculi, a diagnosis also arrived at after endoscopy. Numerous determinations of urinary 5-hydroxyindole acetic acid were normal as were liver function tests. A liver-spleen scintigram showed no indication of metastases. The diagnosis of multiple gastric carcinoid tumors was made on the basis of gastroscopy and histology. Macroscopic examination of the surgical specimen obtained at gastrectomy revealed 31 polyps of the gastric mucosa with diameters of 0.4-2 cm, all of which were histologically carcinoid tumors. The tumor cells were cubic and polygonal with round to oval, eccentrically situated cell nuclei. All carcinoid tumors showed infiltrating growth, and small tumor complexes were detected in the lymphatic spaces. The authors recommend a gastrectomy for multiple gastric carcinoid tumors.

4043 DIVERTICULA OF THE STOMACH--DIAGNOSIS OF THEIR IMPORTANCE. (Ger.) Clemens, M.; Langhans, P.; Heger, R. A.; Safrany, L. (Univ. Allgemeinchirurgie, 4400 Munster/Westf., W. Germany). *Roentgenblaetter* 30(3):126-132; 1977.

The etiology, clinical symptoms, diagnosis, complications, and treatment of diverticula (DV) of the stomach are reviewed. Etiologically they are classified as congenital or true, acquired true, and false DV. The first includes all layers of the gastric wall and are almost always located in the juxtacardiac region. The acquired DV may be separated into those caused by increased intragastric pressure and those caused by traction, especially after inflammatory disease of the pancreas. About 75% of DV are found in the fundus, 15% in the prepyloric antrum, and 10% elsewhere. A 37% coincidence of stomach DV with DV of other sites has been reported, and 80% of stomach DV occur after the age of 40 yr. The clinical symptoms are uncharacteristic; frequent complaints are postprandial epigastric pressure, nausea, vomiting, and heartburn. In most instances, DV are discovered by x-ray examination. Characteristically, there is a smooth outpouching of the wall with an even, often rounded, contour and a narrowed neck. DV retain contrast media, and they may vary in size from a bean to a fist. Diagnosis can be complicated by gastric obstruction of food, mucosa or blood, and in the fundus, pseudodiverticula, hiatal hernias, or gallbladder perforations can lead to a false diagnosis. Treatment is conservative and consists of a bland diet and antacids. Surgery is indicated in large stomach DV and resection if malignancy is present.

4044 NONINVASIVE VASCULAR ASSESSMENT OF DUMPING SYNDROME: USEFULNESS IN THERAPEUTIC DECISIONS.

(Eng.) Creaghe, S. B.; Saik, R. P.; Pearl, J.; Peskin, G. W. (Veterans Admin. Hosp., 3350 La Jolla Village Drive, San Diego, CA 92161). *J. Surg. Res.* 22(4):328-332; 1977.

The vascular effects of vasoactive substances that play a role in postgastrectomy dumping syndrome were measured in eight patients. The presence of true dumping syndrome (versus postvagotomy diarrhea) was established by measuring venous occlusion plethysmography (VOP) volume changes and mercury strain gauge (MSG) finger-tip volume changes. All patients had disabling symptoms of intractable diarrhea, weight loss, vomiting, and/or lightheadedness following ulcer surgery. Their ages ranged from 29 to 60 yr. Each patient underwent a provocation test with the ingestion of 100 g of glucose with the simultaneous measurement of blood pressure, pulse rate, MSG, and finger VOP continuously for 90 min. MSG measurements following glucose challenge demonstrated elevations of 300-1,900% of the control values in five patients; the remaining three patients had peak elevations of only 100-220%. Two of the latter patients and four of the patients with high peak MSG values also underwent simultaneous VOP. The two patients with low MSG volume changes also had low VOP increases (243 and 267%), while the other four patients had increases of 750-2,500% of control. In eight controls who had not undergone gastric surgery, the MSG peaks varied between 171 and 314%, and VOP ranged between 104 and 350%. The three patients with normal MSG and VOP or normal MSG alone all proved to have postvagotomy diarrhea and responded to appropriate treatment. One of the five patients that were diagnosed as having the true dumping syndrome on the basis of these studies benefitted from an interposition procedure; postoperatively, his MSG dropped from 933 to 164% and VOP from 827 to 162%. The measurement of VOP and MSG represents a noninvasive, simple means of assessing the degree of vasodilatation that is presumably secondary to the release of kinin.

4045 DYNAMICS OF ATROPHIC GASTRITIS IN MALE AND FEMALE SUBJECTS AFTER PARTIAL GASTRIC RESECTION--AN EVALUATION BY STOCHASTIC ANALYSIS.

(Eng.) Kekki, M.; Hakkiluoto, A.; Siurala, M. (Pension Insurance Company Ilmarinen, Eerikinkatu 41, 00180 Helsinki 18, Finland). *Scand. J. Gastroenterol.* 11(6):597-601; 1976.

Forty-two subjects were examined for chronic gastritis 17-18 yr following partial gastrectomy for gastric or duodenal ulcer. There were 33 men and 9 women, ranging in age from 44-74 yr (average 60.6 yr) for the men and 57-71 (average 65.4 yr) for the women. Gastroscopic biopsies were obtained, and the state of the mucosa was graded by the following scoring system: 0, normal; 1, superficial gastritis; 2, slight atrophic gastritis; 3, moderate atrophic gastritis; and 4, severe atrophic gastritis (complete or almost complete loss of normal body glands). This score was adjusted for age (age adjusted score, AAS), and the resulting figure represented the degree of progression of chronic gastritis with reference to a random population, independent of the subject's age. The AAS of the 33 male subjects averaged 0.90, which was significantly different in comparison with an average score of -0.17 in male controls ($p<0.001$); the AAS in female subjects and controls did not differ significantly (-0.28 versus 0.01 in controls). The atrophic changes in postgastrectomy patients was not dependent on age. This fact suggests a direct causal relationship between the surgical procedure and gastritis.

4046 PATHOLOGY, CLINICAL APPEARANCE AND THERAPY OF MENETRIER'S DISEASE.

(Ger.) Lenner, V.; Stahlschmidt, M.; Wagner, R.; Neher, M. (Chirurgische Universitatsklinik, Langenbeckstrasse 1, D-6500 Mainz, W. Germany). *Med. Klin.* 72(8):319-325; 1977.

The clinical pathology and therapy of Menetrier's disease in three men are presented. One man presented with hematemesis, epigastric pressure, and a total protein level of 6.6 g%. Gastroscopy revealed giant formations with mucosal hemorrhage layers, especially in the corpus ventriculi. Several biopsies yielded a histological diagnosis of undifferentiated stomach cancer. However, stomach resection showed hyperplastic mucosa in the elongated, cystic gastric foveoli. The gland was atrophic, and the tunica propria showed dense, lymphoplasmic cellular infiltrates and some granulocytes. The second man, who had had a duodenal ulcer, presented with weight loss and epigastric pressure. A histological diagnosis of polypous hyperplasia of the corpus mucosa was made. Surgery disclosed hypertrophic folds and, in places, polypous mucosa in the corpus fundus region in addition to gastric ulcer. A year later, the patient was found to have marked superficial gastritis with foveolar hyperplasia. The third patient had the same histological findings upon biopsy as the second patient, but laparotomy showed no pathological processes on the outside of the stomach. He had a three-fourths gastric resection. Stomach specimens revealed an irregular, built-up mucosa with cystic extension in some places.

The tunica propria was infiltrated with lymphoplasma cells. Although all three patients had Menetrier's disease, each presented with different symptoms. Roentgenologic and endoscopic appearance may contribute to the diagnosis of Menetrier's disease, but only histologic examination is decisive.

4047 GASTRIC SECRETORY FUNCTION IN PATIENTS WITH CHRONIC RENAL FAILURE UNDERGOING MAINTENANCE HEMODIALYSIS. (Eng.) Reisman, T. N.; Perez, G. O.; Rogers, A. I. (Univ. Miami Sch. Medicine, Miami, FL 33125). *Am. J. Dig. Dis.* 21(12):1044-1048; 1976.

Gastric secretion was evaluated in nine male patients with chronic renal failure undergoing maintenance hemodialysis for 15 hr/week. Two patients had low or absent acid output in the basal state, and three of nine patients exhibited hypersecretion (greater than 40 mEq/hr) in response to pentagastrin stimulation (6 µg/kg, i.m.). There were four basal hypersecretors (greater than 5.0 mEq/hr), two of whom had associated peptic ulcer disease. Serum gastrin responses of these patients to a 60-g protein meal were comparable to those of control subjects. Calcium infusion (12 mg/kg calcium gluconate, i.v.) in two nonulcer basal hypersecretors depressed basal acid secretion from 10.9 mEq/hr to an average of 8.9 mEq/hr in one case and from 21.6 mEq/hr to an average of 8 mEq/hr in the other case. A high degree of positive correlation ($p<0.02$) existed between serum parathormone levels and basal acid output. An almost significant positive correlation ($r=0.6559$, $p<0.1$) was observed between fasting serum gastrin levels and basal acid output, suggesting a possible role of gastrin as a stimulant to acid secretion. The results suggest that, while acid secretory abnormalities vary in patients with chronic renal failure on hemodialysis, there is no apparent sensitivity of the gastrin-secreting cells to protein or to calcium ion that might account for acid hypersecretion. Secondary hyperparathyroidism may influence the occurrence of acid secretory abnormalities.

4067 CONCENTRATIONS OF PROSTAGLANDIN A-, E- AND F-LIKE SUBSTANCES IN GASTRIC MUCOSA OF NORMAL SUBJECTS AND OF PATIENTS WITH VARIOUS GASTRIC DISEASES. (Eng.) Schlegel, W.; Wenk, K.; Dollinger, H. C.; Raptis, S. (Universitat Ulm, Steinhovelstrasse 9, 7900 Ulm, W. Germany). *Clin. Sci. Mol. Med.* 52(3):255-258; 1977.

Prostaglandin E-, A-, and F-like compounds were measured in antral biopsy material obtained at endoscopy from 8 normal subjects, 10 patients with gastritis, 10 with chronic atrophic gastritis, 13 with acute gastric ulcer, and 16 with duodenal ulcer. In the normal subjects, the amounts of prostaglandin E- plus A-like material varied from 21 to 83 ng/mg protein, and the amount of prostaglandin F-like material varied from 2 to 17 ng/mg. In patients with gastritis, the concentrations of prostaglandin (E+A)-like substances were 6 times higher, and of prostaglandin F-like substances, 2 times higher than in normal subjects. In chronic atrophic gastritis, the concentration of prostaglandin (E+A)-like substances was 4 times as high as in normal subjects, whereas prostaglandin F-like material remained unchanged. The prostaglandin (E+A)-like material reached concentrations 4 times higher than in normal subjects in acute gastric ulcer, accompanied by a fivefold increase in prostaglandin F-like substances. After healing of the gastric ulcers, the levels of prostaglandin-like substances returned to normal. Gastric mucosal damage may stimulate increased prostaglandin formation in the area of the destroyed tissue. If ulcers develop as a result of prostaglandin deficiency, the normal tissue could counteract by increasing the concentrations of prostaglandin E+A to start the proliferation phase.

4068 SOMATOSTATIN INHIBITS INSULIN-STIMULATED GASTRIN RELEASE AND GASTRIC SECRETION OF ACID, PEPSIN, AND INTRINSIC FACTOR (IF) IN DUODENAL ULCER PATIENTS. (Eng.) Schrumpf, E.; Vatn, M. H.; Hanssen, K. F.; Semb, L. S.; Myren, J. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 11(5):517-520; 1976.

The effect of somatostatin (0.6 mg/hr) on insulin-stimulated gastrin release and gastric acid, pepsin, and intrinsic factor (IF) secretion was examined in six unoperated patients with duodenal ulcer. Insulin (0.15 IU/kg, i.v.)-stimulated acid, pepsin, and IF levels (89 ± 6 mEq/l, 1,064 ± 83 mg/l, and 54 ± 10 U/ml, resp.) were decreased by the simultaneous administration of somatostatin (46 ± 5 mEq/l, $p<0.01$; 999 ± 108 mg/l; and 58 ± 4 U/ml; resp.). Plasma gastrin was also significantly lower after somatostatin infusion. The results indicate that somatostatin inhibits insulin-induced gastrin release and gastrin secretion.

4069 SECRETIN-INDUCED HISTAMINE RELEASE IN DUODENAL-ULCER PATIENTS. (Eng.) Baenkler, H. W.; Mitznegg, P.; Domschke, S.; Wunsch, E.; Subramanian, N.; Domschke, W.; *et al.* (Univ. Erlangen-Nurnberg, Universitatsstrasse 22, 8520 Erlangen, W. Germany). *Lancet* 1(8018):928-929; 1977.

Because many duodenal ulcer patients develop an anaphylactoid skin reaction after the intradermal administration of secretin, skin samples from seven patients with duodenal ulceration and six patients with goiter or cholelithiasis were incubated with tris buffer alone and with tris buffer containing 20 clinical units (CU)/ml synthetic secretin or 100 μg/ml of compound 48/80, which is known to induce histamine release from mast cells. Skin from duodenal ulcer patients released significantly more histamine after secretin treatment than did that of controls (the histamine content induced by secretin was 65.1 ± 27.3% of the initial content in the ulcer patients versus 34.9 ± 6.0% in the controls, $p<0.01$). Histological examination of skin samples from these patients showed that the number of histamine-containing mast cells averaged 5-7 per field and dropped to 1-2 per field after incubation with secretin. It is concluded that, in a certain type of duodenal ulceration, intradermal secretin releases histamine from mast cells and thus induces a local anaphylactic reaction. This reaction might prove suitable for preclinical ulcer diagnosis and/or for detection of patients at risk of acquiring that disease.

4070 GASTROINTESTINAL EFFECTS OF LONG-TERM TREATMENT OF DUODENAL ULCER WITH DEPOT SECRETIN: CLINICAL, SECRETORY, ULTRA-STRUCTURAL, AND ENZYMOLOGICAL ASPECTS. (Eng.) Demling, L.; Domschke, W.; Riemann, J. F.; Domschke, S.; Ruppin, H.; Junge, O.; Wunsch, E. (Dept. Medicine, Univ. Erlangen-Nurnberg, Erlangen, W. Germany). *Scand. J. Gastroenterol.* 11(42):135-145; 1976.

The effects of a long-acting secretin (10 U/kg s.c., b.i.d. for 1 week, daily thereafter) on three men with duodenal ulcers were studied over a period of 4 weeks. Patients reported improvement in epigastric pain as early as 2 days after onset of treatment, and, as shown by duodenoscopy, the ulcers healed completely after 2 weeks in one patient and after 3 weeks in the other patients. Gastric fluid and acid production were not affected by treatment. Pancreatic fluid and bicarbonate production were unchanged compared to pretreatment values. Similarly, intestinal disaccharidase activity remained constant, as did the activities of the dipeptide hydrolases, alkaline phosphatase, and enterokinase. The authors suggest that long-acting secretin has therapeutic potential in healing duodenal ulcers.

4071 PREVENTION AND TREATMENT OF GASTRIC AND DUODENAL ULCERS IN RENAL TRANSPLANT PATIENTS. (Fre.) Launois, B.; Campion, J. P.; Gosselin, M.; Cartier, F. (C.H.U. de Rennes, Hopital Pontchaillou, rue Henri-Le-Guillous, F 25011 Rennes, France). *Gastroenterol. Clin. Biol.* 1(1):23-27; 1977.

Treatment with systemic antacids of 79 renal transplant patients (55 men, 24 women; average age 33.7 yr) for prevention of gastroduodenal ulcers is described. Immunosuppressive therapy consisted of antilymphocytic globulins (10 mg/kg/day i.v. for 10 days than 252 mg/day i.m.), azathioprine (1-2 mg/kg/day), and prednisone (1 mg/kg/day). In patients that rejected transplants, prednisone was supplemented by methylprednisolone (1 g at 48-hr intervals). These drugs were administered with 5.7 g aluminum phosphate or 1 g aluminum hydroxide and 1.19 g magnesium hydroxide daily. Only two subocclusive accidents were attributed to the antacids. However, hyperphosphotemia, greater than 4.5 mg, was noted in 33 patients. No ulcer recurrences were noted in any of the 79 patients. Autopsy in 14/16 patients who died within 1 yr of transplant revealed ulcer complications or acute ulcer in 2. The percentage of ulcer complications in this group was 2.1%, whereas a 5.2% rate is the usual prevalence rate in renal transplant patients.

4072 GASTRIC AND DUODENAL ULCER HEALING UNDER PLACEBO TREATMENT. (Eng.) Scheurer, U.; Witzel, L.; Halter, F.; Keller, H. M.; Huber, R.; Galeazzi, R. (c/o Dr. Charles Code, Veterans Admin. Center, Building 115, Los Angeles, CA 90073). *Gastroenterology* 72(5):838-841; 1977.

The healing time relation of 30 gastric and 15 duodenal ulcers was assessed by repeated endoscopic measurements of ulcer size on days 1, 21, and 42 of a 6-week period, during which a selected population of patients was being treated with a placebo. Antacids in small amounts were only given in case of ulcer pain. There was a linear relation between the absolute initial ulcer size and its reduction with time in incompletely healed ulcers of both types. The percentage reduction from the original size was 71% after 3 weeks in gastric ulcers and 83% in 3 weeks in duodenal ulcers; after 6 weeks, the reductions were 82% and 83%, resp., for the two ulcer types. The healing time course for both types of ulcers followed an exponential function. The calculated half-life was 1.7 weeks for gastric and 1.9 weeks for duodenal ulcers. The number of healed duodenal ulcers observed at the 3-week examination was significantly greater than that of healed gastric ulcers ($p=0.05$). It is concluded that repeated measurements of the ulcer size before complete ulcer healing contribute to an optimal characterization of the healing time course. The calculated half-life of less than 2 weeks makes shorter control intervals reasonable for both types of ulcers. The ulcer half-life appears to be a more accurate criterion of the healing process than is the half-life of complete healing.

4073 24-HOUR INTRAGASTRIC ACIDITY AND NOCTURNAL ACID SECRETION IN PATIENTS WITH DUODENAL ULCER DURING ORAL ADMINISTRATION OF CIMETIDINE AND ATROPINE. (Eng.) Pounder, R. E.; Hunt, R. H.; Vincent, S. H.; Milton-Thompson, G. J.; Misiewicz, J. J. (St. Thomas' Hosp., London SE1 7EH, England). *Gut* 18(2):85-90; 1977.

The possibility that anticholinergic therapy concomitant with cimetidine therapy increases the effect of cimetidine was investigated by measuring the 24 hr intragastric acidity and nocturnal output of acid in four duodenal ulcer patients, each receiving on separate occasions, p.o. cimetidine (1 g/day) and placebo, atropine (2.4 mg/day) and placebo, cimetidine and atropine, or two placebos. Cimetidine alone decreased the mean hourly hydrogen ion activity by 63% of control values, decreased the mean hourly hydrogen ion concentration (total acid) by 41%, inhibited nocturnal acid secretion by 83%, and resulted in half the nocturnal samples being anacidic. Atropine treatment alone had no effect when compared with the controls, and combined treatment with both drugs was not superior to cimetidine alone. Atropine did not affect the absorption of or urinary excretion of cimetidine. Fasting serum gastrin concentrations were not changed by any of the treatments. The combination of cimetidine with an anticholinergic appears to offer no advantage over treatment with the H_2-antagonist alone. Cimetidine is the only potent antisecretory drug that does not cause acute side-effects, and this important advantage would be lost if it were given with a maximal dose of an anticholinergic.

4074 EFFECT OF TRUNCAL VAGOTOMY ON GASTRODUODENAL CONTENT OF GASTRIN. (Eng.) Malmstrom, J.; Stadil, F.; Christensen, K. C. (Rigshospitalet, 2100 Copenhagen, Denmark). *Br. J. Surg.* 64(1):34-38; 1977.

The vagal influence on gastroduodenal gastrin content was studied in duodenal ulcer patients before and after truncal vagotomy. Endoscopic biopsies were assayed for total gastrin concentrations. Antral concentration was 17.0 ± 2.0 μg gastrin/g mucosa in 52 unoperated patients compared with 25.2 ± 3.2 μg in 32 vagotomized patients. In 14 patients studied before and 3 months after vagotomy, antral content was almost doubled (10.9 ± 2.3 and 20.4 ± 2.9 μg resp.; in the duodenal bulb the concentration was 2.4 ± 0.3 μg in 37 unoperated patients and 2.2 ± 0.4 μg in 19 vagotomized patients. In six patients in whom measurements were made throughout the duodenum, gastrin concentrations were significantly lower 3 months after vagotomy. Fractionations of pooled homogenates on Sephadex G-50 showed that gastrin component III (gastrin-17) made up 95% of the antral gastrins before and after operation. In the duodenum, component III constituted over half of the gastrins preoperatively, but only one-third postoperatively. The total amount of gastroduodenal gastrin was considerably increased by vagotomy, and it is well established that in serum the gastrin concentration is also higher postoperatively. The most likely explanation of these findings is that in man, the vagus, directly or indirectly, suppresses gastrin production.

4075 STOMACH CANCER FOLLOWING SURGERY FOR GASTRODUODENAL ULCER: A REPORT OF EIGHT CASES. (Fre.) Francillon, J.; Forest, G.; Tissot, E.; Baudet, B.; Vignal, J. (No affiliation given). *Chirurgie* 103(3):157-168; 1977.

Stomach cancer developed in eight men operated on for gastrointestinal ulcers 4.5-31 yr previously. Initially, the patients had duodenal (3), pyloric (1), or gastric (3) ulcers, and underwent gastrectomy (5) or gastroenteranastomosis (3). The ulcer site was unknown in one patient. Prior to detection of stomach cancer, the patients complained of vomiting, anorexia, weight loss, asthenia, hematemesis, and melena. Most of the tumor specimens were well-differentiated, anaplastic adenocarcinoma. They were situated at the mouth of the anastomosis, on the upper stomach (1), at the antrum (3), or over the entire stomach (1). Of the eight patients, four died 1-16 months after surgery, whereas one patient died of uncontrollable hemorrhage immediately after surgery. Three patients survived and were in good health at a 3-yr follow-up.

4097 EFFECT OF ANTIDIARRHEAL AND ANTIMOTILITY DRUGS ON ILEAL EXCRETA. (Eng.) Kramer, P. (Univ. Hosp., 75 East Newton St., Boston, MA 02118). *Am. J. Dig. Dis.* 22(4):327-332; 1977.

Six ileostomized patients received antimotility and antidiarrheal drugs (codeine sulfate, 15 mg q.i.d.; deodorized tincture of opium, 12 drops q.i.d.; diphenoxylate, 5 mg q.i.d.; propantheline, 15 mg q.i.d.; tincture of belladonna, 1 ml q.i.d.; Sorboquel, 1 tablet q.i.d.; kaopectate, 30 ml, frequency not reported; bismuth subgallate, 1 g q.i.d.; and calcium carbonate, 2 g q.i.d.) to determine whether their normal ileal excreta and that induced by prune juice could be altered. A total of 49 studies were performed, 21 with and 28 without prune juice (200 g/day). Bismuth subgallate was the only drug that significantly reduced the normal ileal excreta ($p<0.05$); this decrease ranged from 8 to 13%. Codeine sulfate decreased the ileal excreta in two of three subjects in either type of study. The third subject was a nonresponder to drugs. Deodorized tincture of opium and diphenoxylate were also effective in some subjects. Calcium carbonate increased ileal excreta and fat excretion.

4098 DESCRIPTIVE EPIDEMIOLOGY OF SMALL-BOWEL ATRESIA IN METROPOLITAN ATLANTA. (Eng.) Safra, M. J.; Oakley, G. P.; Erickson, J. D. (Center for Disease Control, Public Health Service, Atlanta, GA 30333). *Teratology* 14(2):143-150; 1976.

The epidemiological characteristics of 46 cases of congenital small bowel atresia in Atlanta, Georgia are reported. The incidence rate was 2.7/10,000 live births. Three occurrences of the malformation, all duodenal lesions, were in infants with Down's syndrome, one was in an infant with cystic fibrosis, and ten were in infants with other major anomalies apparently morphogenetically unrelated to small bowel atresia. The remaining 32 infants were considered to have isolated small bowel atresia. Seven of the infants with isolated small bowel atresia are known to have died by 1 yr of age (fatality ratio of 21.9%). The defect was significantly associated ($p<0.001$) with low birth-weight. Among the 32 cases of isolated small bowel atresia, 19 infants, including 6 of the 7 that died, weighed less than 2,500 g at birth. Isolated small bowel atresia showed no sex predilection. The defect occurred twice as frequently in blacks (3.1/10,000 livebirths) as in whites (1.4/10,000), with the difference being due to a higher than expected incidence in black females (4.6/10,000). The incidence of the defect was highest in the winter months. Duodenal lesions occurred in 31%, jejunal lesions in 41%, ileal lesions in 13%, and other or unspecified lesions in 16% of the 32 isolated small bowel atresia cases. Except for the association of Down's syndrome with duodenal atresia, no specific patterns of associated anomalies were seen for either duodenal or jejunoileal atresia. The inability to divide the atresias into two clearly distinct epidemiological groups on the basis of lesion location is perhaps an indication of the heterogeneity of both groups of disorders with respect to etiology and pathogenesis.

4099 PRIMARY DUODENAL CARCINOMA WITH PROTEIN-LOSING ENTEROPATHY. (Eng.) Mangla, J. C.; Taylor, E.; Cristo, C. (Monroe Community Hosp., 435 E. Henrietta Rd., Rochester, NY 14603). *Am. J. Gastroenterol.* 67(1):73-76; 1977.

The case is reported of a patient with a primary duodenal carcinoma and protein-losing enteropathy. The patient, a 71-yr-old man, presented with weakness and edema; a mass in the head of the pancreas that was presumptively diagnosed as carcinoma had been previously found. Gastroscopy showed an ulcerated lesion in the duodenum that subsequently proved to be a primary carcinoma with marked lymphangiectasia. The total protein level was 4.3 g/100 ml, and the albumin level was 1 g/100 ml. The Zollinger-Ellison syndrome was ruled out by normal gastrin levels. Radioactive albumin studies revealed 10% albumin excretion in a 96-hr stool collection. It was decided that these studies should be repeated with continuous nasogastric aspiration in order to exclude the possibility of protein loss from gastric mucosa. However, the patient died from a pulmonary embolus before the test was repeated. Autopsy revealed duodenal adenocarcinoma, pancreatic atrophy, anasarca, and generalized arteriosclerosis. There was no significant hypertrophy of the gastric mucosa or any evidence of ulceration. It seems likely that the protein loss occurred from the duodenal carcinoma.

4100 GASTROINTESTINAL AND METABOLIC FUNCTION IN PATIENTS WITH THE CARCINOID SYNDROME. (Eng.) Feldman, J. M.; Plonk, J. W. (Box 2963, Duke Univ. Medical Center, Durham, NC 27710). *Am. J. Med. Sci.* 273(1):43-54; 1977.

Gastrointestinal absorption was studied in six consecutive patients with metastatic serotonin-secreting carcinoid tumors. One patient had a consistent defect in fat absorption, and two other patients malabsorbed fat during spontaneous or dopamine-induced exacerbation of the carcinoid syndrome. The steatorrhea of the patient with the persistent defect in fat absorption was reduced when tumor serotonin production was reduced by parachlorophenylalanine. The six patients had normal hemoglobin levels, and the serum concentration of the following urinary constituents was normal in most of the patients: albumin, carotene, 25-hydroxycalciferol, parathyroid hormone, calcitonin, calcium, phosphorous, osteogenous alkaline phosphatase, cholesterol, triglycerides, and serum lipoproteins. The excretion of the following urinary constituents was also normal in most of the patients: creatinine clearance, tubular reabsorption of phosphorus, calcium, D-xylose, cyclic adenosine 3'5'-monophosphate, and hydroxyproline. Patients with the carcinoid syndrome may have steatorrhea, and their hyperserotoninemia plays a role in this process.

4101 ANGIOGRAPHIC FINDINGS IN CARCINOID TUMORS OF THE SMALL INTESTINE (TWO CASES). (Fre.) Pistolesi, G. F.; Caresano, A.; Del Favero, C.;

Frasson, F.; Fugazzola, C. (Service de Radiologie, Centre Hospitalier et Universitaire, 37100 Verona, Italy). *J. Radiol. Electrol. Med. Nucl.* 57(10):725-731; 1976.

The advantages of using angiography (AN)-(versus conventional radiology) in the diagnosis of carcinoid tumors (CT) were evaluated in two patients, and compared to findings reported in the literature. Clinically, both patients presented with marked hepatomegaly, fever, diarrhea, dyspepsia, and anorexia. In the first patient, barium transit showed no organic lesions. A second barium transit revealed an endoluminal lacunar image. In the second patient, this procedure showed only ulceration of the intestines. AN in both patients, however, revealed a reduction in the diameter of the mesenteric trunk and middle right colic branches, plus interruption of the marginal arterial branches. Multiple hypervascular metastases of part or all of the liver were seen. Surgery and histology confirmed the presence of CT. There is no overall agreement in the literature concerning the angiographic appearances of CT. The small haphazardly arranged arterial vessels, indicative of primary intestinal neoplasms, are not always visible, and the accumulation of contrast medium is generally discrete. The degree of vascularization of CT also varies. Often reflux is totally absent or, at least, not intense. The first patient demonstrated discrete intratumor vascularization but only a small accumulation of contrast medium at the parenchymatous stage. The second patient showed a rounded nodule with distinct borders that was opacified at the periphery. Nevertheless, AN is recommended over barium passage, since it can reveal information on the nature of these lesions.

4102 SILENT PYLORO-DUODENAL GASTRINOMAS: REPORT OF THREE CASES. (Fre.) Berger, G.; Patricot, L. M.; Guillard, M. T.; Beurlet, J.; Frappart, L.; Vauzelle, J. L. (Hopital cardiologique, B. P. Lyon Montchat, 69394 Lyon Cedex 3, France). *Ann. Anat. Pathol. (Paris)* 22(1):5-20; 1977.

Three cases of silent pyloro-duodenal gastrinomas that secreted gastrin but did not evoke clinically the Zollinger-Ellison syndrome are reported. In two women, aged 48 and 60 yr, the tumor developed in the submucosa of the duodenal bulb. It appeared in the submucosa of the pyloro-bulbar region in a 73-yr-old woman. The patients presented with epigastric pain, dyspepsia, nausea, or diarrhea. Endoscopy confirmed the presence of the benign tumors that were excised by gastrectomy or pylorotomy. Two of the three tumor specimens were ulcerated. Histiochemistry showed endocrine secretion granules and the silver staining technique of Grimelius revealed argyrophile granules in a large number of tumor cells, which may correspond to the neurosecretory granules observed ultrastructurally in the tumor cells of one patient. Immunofluorescence detected immunoreactive gastrin in most of the tumor cells of all three patients. Apparently these tumors arise from the gastrin cells of the mucosa or from their precursors. The detection of immunoreactive gastrin in the cells is the main diagnostic tool.

4103 INTRAMURAL HEMATOMAS OF THE DIGESTIVE TRACT COMPLICATING ANTICOAGULANT THERAPY. TWO NEW CASES (ONE DUODENO-JEJUNAL, THE OTHER ILEOCECAL) CURED BY INTESTINAL RESECTION. (Fre.) Reynier, J.; Merlat, M.; Aurousseau, R.; Bernard, J. L.; Grossetti, D.; Monod, R.; Chollier, A. (Hopital Boucicaut, 78, rue de la Convention, 75730 Paris Cedex 15, France). *Ann. Chir.* 31(2):169-176; 1977.

The results of surgery for intramural hematoma (IH) of the small intestine in a 47-yr-old woman and a 65-yr-old man, both on long-term therapy with dicoumarol, are presented. IH was characterized by severe abdominal pain in both patients accompanied by nausea and vomiting that progressed to an occlusive syndrome. In the first patient, IH was localized in the duodenum and jejunum, and it was treated by segmental duodenojejunectomy followed by duodenojejunal anastomosis. A radiological examination 6-months postoperatively showed a normal intestinal transit and absorption. In the second patient, IH occurred in the ileum and cecum and was treated by right hemicolectomy. Previously, the patient suffered a myocardial infarction and was treated with acenocoumarol that was resumed postoperatively together with heparin. At 3-months follow-up, the patient was in good condition with radiological evidence of satisfactory function of the anastomosis.

4104 MEDITERRANEAN LYMPHOMA (DIFFUSE IMMUNOBLASTIC SMALL INTESTINAL LYMPHOMA) WITHOUT IgA ABNORMALITY. (Fre.) Galian, A.; Scotto, J.; Rouffy, J.; James, J. M.; Lenormand, Y.; Rambaud, J. C. (Hopital Saint-Lazare, 107, rue du Faubourg-Saint-Denis, F 75475 Paris Cedex 10, France). *Gastroenterol. Clin. Biol.* 1(1):49-58; 1977.

A case of Mediterranean lymphoma (diffuse immunoblastic small intestine lymphoma) without IgA abnormality is reported in a 22-yr-old Algerian man. The patient had a 6-yr history of abdominal pain and diarrhea. He presented with cachexia, edema of the legs, pleural and pericardial effusions, an abdominal mass, and enlarged axillary nodes. Biological tests revealed a malabsorption syndrome, but no serum immunoglobulin abnormalities. Biopsy of the pleura revealed sarcomatous cells and a biopsy of the axillary nodes confirmed the existence of a malignant lymphoma. The patient deteriorated rapidly and died of a widespread hemorrhagic syndrome. Microscopy revealed immunoblast proliferation, which had infiltrated the entire small intestinal wall and had destroyed the normal axillary and mesenteric lymph node architecture. Portal triads and serous effusions also contained immunoblasts, a few of which tended to plasmocyte differentiation. Immunofluorescence revealed no intracytoplasmic immunoglobulin. It is suggested that, besides alpha-chain disease, Mediterranean lymphoma also includes other histological types of diffuse intestinal lymphomas.

4105 INTESTINAL LYMPHANGIECTASIA. (Fre.) Rosenberg, D.; Peytel, J.; Floret, D.; Monnet, P. (Hopital Edouard-Herriot, 69003, Lyon, France). *Pediatrie* 31(8):795-802; 1977.

A case of intestinal lymphangiectasia in an infant girl and a 3-yr follow-up are presented. At birth the girl presented with subpubic edema; she was hospitalized at 1 month of age. At 4.5 months, edema was pronounced as a result of moderate ascites; gastrointestinal symptoms included diarrhea and steatorrhea. Biological tests confirmed exudative enteropathy that led to a diagnosis of intestinal lymphangiectasia with characteristic features of hypoproteinemia, hypocalcemia, and lymphocytopenia. An ascites tap revealed chylous liquid indicative of anomalies of the lymph duct. Of three jejunal biopsies, only the first showed type II-III atrophy. Lymphangiectasia was not apparent at the level of the villi; however, biopsies were not performed in the submucosa. Lymphangiography was normal and radiological and isotope studies showed protein loss into the gastrointestinal tract. Treatment with medium chain triglycerides reduced edema and weight loss; however, in the long term had no curative effect on steatorrhea and persistent biological changes. Growth retardation and immune deficiency did not improve.

4106 MORPHOLOGICAL AND FUNCTIONAL CHANGES OF THE LIVER FOLLOWING SMALL INTESTINAL BYPASS FOR OBESITY.

(Eng.) Solhaug, J. H.; Gluck, E. (Dept. Surgery, Haukeland Hosp., Bergen, Norway). *Scand. J. Gastroenterol.* 11:793-800; 1976.

Studies were made to correlate the histological changes in liver structure with changes in liver function after an ileo-bypass operation for the treatment of obesity in six patients. Liver biopsies of one man and five women were obtained at the time of jejuno-ileal bypass and compared with liver biopsies obtained at 6, 12, and 18 months after the operation. The extent of fatty changes, cellular infiltration, connective tissue infiltration, and parenchymal cell damage was recorded. The weight loss in all patients followed a similar pattern, with an initial rapid loss in the immediate postoperative period and a nearly exponential loss up to 12 and 18 months after the operation. Increasing steatosis and hepatic cellular damage were found in all patients during the period of most rapid weight loss. With reduced rate of weight loss the steatosis decreased, and eventually a nearly complete clearing of fatty infiltration occurred. Preoperatively, none of the applied function tests was able to reveal the concomitant changes in liver histology. Postoperatively, the BSP retention test and the glutamylpyruvic transaminase activity in serum nearly paralleled the increased fatty infiltration and the hepatic cellular damage seen in the biopsies. No correlation was seen in serum γ-glutamyl transpeptidase activity, alkaline phosphatase activity, or total bilirubin level, or in the galactose elimination test except in one patient who postoperatively developed serious liver damage and cirrhosis. These tests, therefore, were useless in predicting actual morphological changes. The results indicate that the bypass operation may be followed by considerable changes in liver morphology that are reflected only to a minor degree by standard liver function tests. To detect concurrent morphological changes necessitating additional therapy, repeated liver biopsies are recommended after the operation.

4107 INTESTINAL ADAPTATION AFTER JEJUNO-ILEAL BYPASS OPERATION FOR MASSIVE OBESITY.

(Eng.) Iversen, B. M.; Schjonsby, H.; Skagen, D. W.; Solhaug, J. H. (Medical Dept. A, Univ. Bergen, Bergen, Norway). *Eur. J. Clin. Invest.* 6(5):355-360; 1976.

Intestinal adaptation was studied in six patients with massive obesity who were treated by jejuno-ileal bypass operation. Surgery consisted of bypass of the major part of the small intestine with an end-to-end anastomosis between the proximal 20 cm of the jejunum and the distal 25 cm of the ileum. At a glucose concentration of 66 mM, the mean glucose absorption rate (as measured by a perfusion technique) 6 months after surgery (472 μmol/min/0.2 m jejunum) was not significantly different from the mean absorption rate before surgery (395 μmol/min/0.2 m jejunum). However, at a glucose concentration of 133 mM, the mean glucose absorption rate increased significantly ($p<0.025$) from a preoperative value of 651 to a postoperative value of 1,011 μmol/min/0.2 m jejunum. Mean lactase activity was significantly increased in the jejunum (27.0 ± 11.0 before and 47.5 ± 13.0 U/g protein after surgery, $p<0.025$) and in the ileum (4.2 ± 3.9 before and 18.5 ± 6.4 U/g after surgery, $p<0.005$) 6 months after surgery, whereas the mean sucrase activity did not change significantly. There was a significant increase in the mean villus height in the jejunum (451 ± 97 μ before and 559 ± 164 μ after surgery, $p<0.025$) and in the ileum (441 ± 102 μ before and 609 ± 156 μ after surgery, $p<0.05$) 6 months after surgery; but the epithelial cell height and width were unchanged in both the jejunum and the ileum, suggesting that the operation resulted in epithelial cell hyperplasia. The mean crypt length did not change in the jejunum but showed a significant increase in the ileum (121 ± 36 μ before and 169 ± 1 μ after surgery, $p<0.05$). There was a significant correlation between glucose absorption and villus height in the jejunum when the glucose concentration in the perfusate was either 66 mM ($r=0.69$) or 133 mM ($r=0.76$), suggesting that the increased glucose absorption was related to an increased number of epithelial cells.

4108 BILE SALT METABOLISM FOLLOWING JEJUNOILEAL BYPASS FOR MORBID OBESITY.

(Eng.) Stein, T. A.; Wise, L. (Washington Univ. Sch. Medicine, St. Louis, MO). *Ann. Surg.* 185(1):67-72; 1977.

Bile salt pool size and kinetics were evaluated in eight women with morbid obesity (mean weight, 124.4 ± 16.3 kg) before and after jejunoileal bypass. The operation consisted of an end-to-end anastomosis of 35 cm of proximal jejunum to 10 cm of terminal ileum and an end-to-end side anastomosis of the excluded segment of small bowel to the cecum. Preoperative glycocholic acid pool size, turnover rate/day, and loss/day values were 1.38 ± 0.32 g, 0.85 ± 0.60, and 0.97 ± 0.64 g, resp., as compared with corresponding postoperative values of 0.56 ± 0.38 g, 5.87 ± 4.57, and 2.77 ± 2.36 g, resp. All of these changes were significant ($p<0.01$). Preoperative glycochenodeoxycholic acid pool size, turnover rate/day, and loss/day values were 0.90 ± 0.25 g, 0.67 ± 0.53, and 0.56 ± 0.37 g, resp., as compared with postoperative values of 0.42 ± 0.27 g, 3.70 ± 2.79, and 1.15 ± 0.86 g, resp. ($p<0.01$, $p<0.01$, and $p<0.05$, resp.). The results indicate that glycocholic acid metabolism was altered more than glycochenodeoxycholic acid metabolism after jejunoileal bypass, with the chenodeoxycholate pool decreasing less than the cholate pool in spite of greater cholate synthesis. Although all patients received identical surgery, the effect on bile salt kinetics and pool sizes varied among the patients. It is suggested that the long-term effects of jejunoileal bypass on bile salt metabolism and the associated complications of the procedure are dependent on the individual patient's capability for increased hepatic synthesis of bile salts and on the adaptability of the remaining small bowel for increased reabsorption of bile salts.

4109 FUNCTIONAL INTESTINAL OBSTRUCTION DUE TO DEFICIENCY OF ARGYROPHIL NEURONES IN THE MYENTERIC PLEXUS: FAMILIAL SYNDROME PRESENTING WITH SHORT SMALL BOWEL, MALROTATION, AND PYLORIC HYPERTROPHY.

(Eng.) Tanner, M. S.; Smith, B.; Lloyd, J. K. (Hosp. for Sick Children, Grant Ormond St., London, England). *Arch. Dis. Child.* 51(11):837-841; 1976.

Three case reports are described of infants with a syndrome of pyloric hypertrophy, short small intestine, malrotation, and functional obstruction of the bowel due to peristaltic failure associated with faulty development of the myenteric plexus. The main histological features of the syndrome are: the failure of ganglion cell fall-out, which normally occurs around birth, along with the presence of too many neurons in the ganglia, the presence of many neuronal nuclei which have the clumped chromatin characteristic of neuroblasts, and the absence or reduction of intrinsic argyrophil ganglion cells and their processes. In one case, the abnormality of motility associated with the absence of the argyrophil plexus was demonstrated radiologically where to-and-fro movement of barium in the upper small bowel was clearly seen. The motility was also reflected as a markedly delayed transit time. The diagnosis of the syndrome of argyrophil neuron deficiency is unlikely to be made before laparotomy unless a previous child has been affected. The marked thickening of the bowel wall is indicative of the underlying neural abnormality; and, if an ileostomy is performed, it is possible, without added risk, to obtain 2-3 cm of ileum upon which a histological diagnosis may be made. In the absence of the argyrophil plexus, ongoing peristalsis cannot be effected by pharmacological stimulation of either the nerve cells or the muscle fibers, and the condition is thus incompatible with life. Thus, long periods of i.v. nutrition seem inappropriate. A review of the above three cases along with four previously reported cases of infants with similar clinical features reveals that in this small group there were two pairs of siblings and one other child who was the product of a doubly consanguineous marriage; these facts strongly suggest that the disorder is inherited as an autosomal recessive.

4110 SCLEROSING PERITONITIS DUE TO PRACTOLOL.

(Eng.) Thompson, R. P. H.; Jackson, B. T. (St. Thomas Hosp., London SE1, England). *Br. Med. J.* 1(6073):1393-1394; 1977.

Six patients are discussed who developed intestinal obstruction from sclerosing peritonitis after practolol treatment. All patients (aged 55-63 yr) were treated with practolol (100 mg, 3-4 times/day) for angina or paroxysmal tachycardia. Ocular and skin changes caused by the drug occurred in all patients. All patients presented with symptoms of obstruction that were not relieved by conservative treatment. Four patients also had a palpable abdominal mass caused by a matted small intestine cocooned in the characteristic fibrous membrane. Repeated laparotomies, causing infection and conventional postoperative adhesions, confused the characteristic appearances and made recognition and removal of the membrane difficult in one patient. In this patient, the fibrous membrane was not restricted to a cocoon around the small bowel, but also caused large bowel peritoneal thickening and colonic obstruction. The membrane extended onto the large bowel in three further patients and onto the stomach in two of these. There was no gastric or large bowel obstruction in these three patients. A pleural effusion developed in one patient and pleural thickening occurred in two others. Complete stripping of the membrane was carried out in all patients. The symptoms completely resolved in three patients, one of whom has been followed for 16 months after surgery; three patients have mild abdominal symptoms. Sclerosing peritonitis should be considered in all patients with subacute intestinal obstruction who have taken practolol.

4111 ENDOSCOPIC POLYPECTOMY FROM THE AFFERENT DUODENAL LOOP.

Malabsorption

4129 RELATIONSHIP BETWEEN CHANGES IN INTRALUMINAL PRESSURE AND TRANSMURAL POTENTIAL DIFFERENCE IN THE HUMAN AND CANINE JEJUNUM IN VIVO.

(Eng.) Read, N. W.; Smallwood, R. H.; Levin, R. J.; Holdsworth, C. D.; Brown, B. H. (Dept. Medicine, Univ. Sheffield, Sheffield S10 2TN, England). *Gut* 18(2):141-151; 1977.

The possibility that the fluctuation in transmural potential difference (PD) seen in the human jejunum *in situ* is related to intestinal motility was tested by recording the transmural PD and intraluminal pressure at the same site in both the proximal jejunum in conscious humans and jejunal loops of conscious dogs. In 25 of 31 subjects (7 normal controls and 24 patients under investigation for malabsorption, 6 of whom had celiac disease), a clear association between these fluctuations and changes in intraluminal pressure was observed. The most frequent PD changes were associated with type III pressure waves. These consisted predominantly of large waves (3.1 ± 0.1 mV, mean ± SEM, n=317) that reached maximal amplitude approximately 45 sec after the pressure peak and had a duration of 120 ± 3 sec, but also included less frequent spikes (0.5 ± 0.1 mV, n=110) concurrent with the pressure wave with a duration of 5 ± 1 sec. Although the type III pressure waves appeared to be propagated aborally at a median rate of 60 cm/min at two sites in the jejunum, the apparent rates of propagation of the corresponding PD waves were much more variable. The largest PD changes (7.8 ± 0.4 mV, n=19), lasting several minutes, were found in association with runs of type I waves (basic rhythm) superimposed on a type III wave. Both pressure and PD activities were suppressed by i.m. propantheline bromide. Intraluminal pilocarpine caused a transient rise in PD not always accompanied by a change in pressure. Distension of the jejunum by rapid injection of a bolus of isotonic sodium chloride produced a delayed rise in the PD that could be prevented by prior administration of propantheline bromide. Experiments using Thiry-Vella loops of proximal jejunum in conscious dogs confirmed the effect of jejunal distension on the PD and also demonstrated that spontaneous retching is preceded by an increase in the PD. It is proposed that the larger spontaneous fluctuations in transmural PD in the jejunum of conscious man are caused by changes in electrogenic secretion associated with intestinal motility and mediated by cholinergic mechanisms. The possible association of increased secretory activity with motility may have functions of lubrication as well as diluting and mixing the chyme for easier digestion and absorption.

4130 USE OF PEROXIDASE-LABELLED ANTIBODIES FOR ULTRASTRUCTURAL LOCALIZATION OF IMMUNOGLOBULINS IN NORMAL AND COELIAC INTESTINAL MUCOSA.

(Eng.) Labbe, F.; Labbe, J. P.; Jos, J. (Hopital des Enfants-Malades, 149 Rue de Sevres, 75730 Paris Cedex 15, France). *In: Immunoenzymatic Techniques. Proceedings of the First International Symposium on Immunoenzymatic Techniques, held in Paris, 2-4 April, 1975.* (New York: American Elsevier): INSERM Symposium No. 2, pp. 281-290; 1976.

Peroxidase-labeled rabbit anti-human α-chain antibody was used in the ultrastructural localization of IgA in duodenojejunal biopsies from normal controls and from children with active celiac disease. Peroxidase-labeled goat anti-mouse IgA and free peroxidase solution were used as controls. Satisfactory penetration of the peroxidase-conjugated antibodies occurred after 24 hr of fixation in 4% formaldehyde at 4 C, followed by incubation of thick frozen sections in the labeled antibody for 16 hr at 4 C or 5 hr at 20 C with continuous stirring. Electron microscopy of normal mucosae revealed many IgA plamsa cells with antibody, which appeared as dense depositis of reaction product, in the perinuclear space and in the endoplasmic reticulum. The mucosae of children with active celiac disease differed from that of the controls in having an increased number of IgA plasma cells with heavy deposits of reaction product on the basement membrane of the surface epithelial cells and the wall of blood vessels. The results confirm that the pathway of mucosal production and secretion of IgA is that IgA produced by plasma cells is transported through the basement membrane of crypt and surface epithelium into the intercellular spaces where, after combination with the secretory piece to form 11 S IgA, it enters the lower part of the epithelial cells before reaching the intestinal lumen.

4131 FAMILIAL ASPECTS OF COELIAC DISEASE. (Eng.)

Stokes, P. L.; Ferguson, R.; Holmes, G. K. T.; Cooke, W. T. (Waikato Hosp., Hamilton, New Zealand). *Q. J. Med.* 45(180):567-582; 1976.

The incidence of celiac disease was determined among first-degree relatives of 115 patients with this disease, and the question of whether any symptom or laboratory finding other than jejunal biopsy could be used in the diagnosis was investigated. The index cases ranged between 9 and 75 yr old. Of 324 relatives, 182 underwent jejunal biopsy; 41 had celiac disease. One-third were asymptomatic, but all had at least one abnormal result among the laboratory indices used. Twenty-two percent of the relatives with a hemoglobin level less than 13.0 g; 43% with a serum folate level less than 3.0 pg/ml; and 24% with a serum albumin level less than 4.0 g/100 ml, serum iron less than 60 μg/100 ml, or with serum alkaline phosphatase above 13 King-Armstrong U had celiac disease. Less than 5% of the relatives with histocompatibility (HLA) antigens other than HLA 8 had celiac disease compared with one in four of those with HLA 8. The high percentage of relatives with HLA 8 antigens or with anticonnective tissue antibodies among those with nonspecific biopsy appearances suggests that these groups also contain a number of relatives with varying degrees of gluten intolerance.

4132 SUGAR ABSORPTION BY SMALL BOWEL BIOPSY SAMPLES FROM PATIENTS WITH PRIMARY LACTASE DEFICIENCY AND WITH ADULT CELIAC DISEASE. (Eng.) Beck, I. T.; Dinda, P. K.; Da Costa, L. R.; Beck, M. (Hotel Dieu Hosp., Queen's Univ., Kingston, Ontario K7L 3H6, Canada). *Am. J. Dig. Dis.* 21(11):946-952;

The absorption of 3-*O*-methyl-D-glucose (3MG) by jejunal biopsies from three normal human subjects was compared with that by everted rings of hamster (n=8) and rat (n=8) jejunum. Also, sugar absorption by human jejunal biopsies from three normal patients was compared with that by jejunal biopsies from five patients with primary lactase deficiency and five patients with adult celiac disease. The affinity of carrier for 3MG (the apparent K_m) did not differ significantly among normal humans, hamsters, and rats. The capacity of 3MG carriers (the V_{max}) was similar in normal humans and hamsters, but significantly lower in rats. The apparent K_m for 3MG transport was identical in normal and lactase-deficient subjects; the V_{max} for 3MG was substantially, but not significantly, higher in the lactase-deficient patients. Michaelis-Menten kinetics were not observed in patients with celiac sprue. Since the intercellular 3MG concentration in these biopsies exceeded the 3MG concentration in the incubation medium, active transport with low saturation kinetics was inferred. This phenomenon suggests that, in celiac sprue, the number of sugar carrier molecules is diminished and that those that do exist have reduced sugar affinity. The latter condition improved in some patients after treatment with a gluten-free diet.

4133 THREE-DIMENSIONAL RECONSTRUCTION OF JEJUNAL BIOPSY IN TROPICAL SPRUE. (Eng.) Mehta, S. K.; Chakravarti, R. N. (Postgraduate Inst. Medical Education and Res., Chandigarh, India). *Am. J. Dig. Dis.* 22(3):223-229; 1977.

A three-dimensional clay model was constructed of a jejunal biopsy from a patient with tropical sprue. The model was constructed from paper tracings of 350 10-μm serial sections of the jejunum. Morphology of villi varied throughout the biopsy segment from a normal appearance to grossly abnormal. Abnormalities of villi are described, including changes in shape, indicating atrophy; infiltration with inflammatory cells; fusion; an increase in goblet cells; and alterations in epithelial cells. Biopsy from a second patient with tropical sprue confirmed these observations.

4134 ENDEMIC TROPICAL SPRUE IN RHODESIA. (Eng.) Thomas, G.; Clain, D. J. (Dept. Medicine, Univ. Rhodesia, Salisbury, Rhodesia). *Gut* 17(11): 877-887; 1976.

Thirty-one cases of tropical sprue were reported in Rhodesia during a 15-month period from among 48 patients with megaloblastic anemia and 3 patients with diarrhea and weight loss. The patients presented with a high incidence of anemia (81%, hemoglobin levels were 2.7-11.7 g), weakness (83%), dyspnea (77%), weight loss (71%), diarrhea (48%), abdominal pain (48%), anorexia (48%), and malnutrition. Electrolyte depletion and hypoalbuminemia occurred frequently. Some patients were grossly dehydrated, and one had osteomalacia. Glossitis and stomatitis were observed in one patient each. No jejunal biopsies were normal, and all showed villous stunting and chronic inflammatory cell infiltrate. Malabsorption of fat, xylose (<5.0 g), and vitamin B_{12} (<0.75%) were found in all patients. Gastric involvement consisting of atrophic (6 cases) or chronic gastritis (7 cases), achlorhydria (10 cases), or hypochlorhydria (14 cases) occurred in 75% of patients. Low overall incidence of steatorrhea (40%) was explained by the inadequate fat content of the diets early in the study. Therapy consisted of tetracycline (250 mg, q.i.d.) alone or in combination with folic acid (5 mg, t.i.d.) and vitamin B_{12} (1,000 μg/month for 6 months) or vitamin B_{12} and folic acid for 6 months followed by tetracycline for 6 months. Clinical and hematological recovery of all patients, with increases of serum albumin, folic acid, and vitamin B_{12} values occurred with tetracycline therapy alone in nine patients, with no change of home diet. One patient died after 3 weeks of treatment. No incidence of relapse occurred on completion of treatment. It is suggested that the search for tropical sprue should not be confined to humid coastal areas, but should encompass the whole continent of Africa.

4135 TROPICAL ENTEROPATHY IN RHODESIA. (Eng.) Thomas, G.; Clain, D. J.; Wicks, A. C. (Dept. Medicine, Univ. Rhodesia, Salisbury, Rhodesia). *Gut* 17(11):837-924; 1976.

The occurrence of tropical enteropathy in Rhodesia is examined. Jejunal abnormalities were reported in Rhodesians of all social and racial categories. Xylose malabsorption was related to socioeconomic circumstances, but not to race. Upper socioeconomic-level Africans and Europeans excreted significantly ($p<0.001$) more xylose (7.2 g) than lower socioeconomic-level Africans (5.4 g). However, no difference between urban and rural Africans of lower socioeconomic status was reported. Vitamin B_{12} and fat absorption were normal, suggesting predominant involvement of the proximal small intestine. It is suggested that repeated gastrointestinal infections or some other environmental factors (diet and sanitation) might be responsible for tropical enteropathy.

4136 SARCOIDOSIS AND WHIPPLE'S DISEASE. ASSOCIATION? CORRELATION? (Fre.) Pequignot, H.; Morin, Y.; Grandjouan, S.; Guerre, J.; Liot, F.; Deslignieres, S.; Duflo, B. (Clinique medicale, Hopital Cochin, 27, rue du Faubourg-Saint-Jacques, F75674 Paris Cedex 14, France). *Ann. Med. Interne (Paris)* 127(11):797-806; 1976.

Based on experience with a patient with sarcoidosis and Whipple's disease, a possible relationship between the two disorders is discussed. A literature review of 54 cases of Whipple's disease with pleuropulmonary lesions made it possible to associate numerous examples of extraintestinal involvement in the latter. The histological appearance of a nonspecific epithelioid granuloma does not indicate a diagnosis of Whipple's disease during the long preintestinal phase. On the other hand, the presence of pleuropulmonary lesions leads to an initial diagnosis of probable sarcoidosis. It is suggested that the appearance of sarcoidosis should be followed by intestinal or mesenteric node biopsy to seek macrophages with a highly PAS-positive cytoplasm characteristic of Whipple's disease, whose discovery requires long-term antibiotic therapy.

4137 IMMUNOLOGICAL ASPECTS OF WHIPPLE'S DISEASE: REPORT OF 4 CASES WITH AN IMMUNOFLUORESCENT STUDY OF THE SMALL INTESTINE. (Fre.) Le Bodic, L.; Le Bodic, M. F.; Delumeau, G.; Hamza, H.; Prost, A.; Leportz, J.; Lenne, Y.; Mussini-Montpellier, J. (Laboratoire d'Anatomie Pathologique, Faculte de Medecine, 1, rue Gaston-Veil, F 44035 Nantes Cedex, France). *Gastroenterol. Clin. Biol.* 1(1):9-21; 1977.

Humoral and cellular immunity serum studies as well as histological, ultrastructural, and immunofluorescent studies of the small intestine were performed in four patients with Whipple's disease. Clinically, all patients presented with arthralgia, diarrhea, adenopathy and sometimes skin pigmentation. Elevated serum IgA levels that returned to normal after treatment (unspecified) were observed in two patients. Conversely, decreased serum IgM levels were noted in two patients. Immunofluorescent studies of biopsy material of the small intestine revealed normal concentrations of immunocytes, but abnormal distribution, since IgA immunocytes were decreased and IgG immunocytes increased. After 6 months of treatment, the number of intestinal IgA immunocytes increased and surpassed normal levels. Disorders of cellular immunity were much more marked and persisted during antibiotic (unspecified) treatment. Although total number of lymphocytes were decreased in only one patient, the E rosette test remained lower than normal before and after treatment in all four patients. Diminished response to delayed skin hypersensitivity tests and lymphocyte transformation by phytohemagglutinin were also observed. Decreased cellular immunity may be directly responsible for Whipple's disease.

4138 DRUG ABSORPTION IN GASTROINTESTINAL DISEASE WITH PARTICULAR REFERENCE TO MALABSORPTION SYNDROMES. (Eng.) Parsons, R. L. (Guy's Hosp. Medical Sch., St. Thomas St., London SE1 9RT, England). *Clin. Pharmacokinetics* 2(1):45-60; 1977.

4139 MINIMAL FORM OF CELIAC DISEASE IN THE ADULT. RADIOLOGIC STUDY OF THE DUODENO-JEJUNUM AND PER ORAL SMALL INTESTINAL BIOPSY. (Fre.) Debray, C.; Cerf, M.; Marche, C.; Le Canuet, R.; Kallal. 4147 INTESTINAL BACTERIAL FLORA OF PATIENTS WITH COLONIC DISEASE. STUDY OF SAMPLES OBTAINED BY COLONOSCOPY. (Fre.) Boisson, J.; Brisou, J.; Brangier, J. (Hopital du Bon-Secours, 75014 Paris, France). *Sem. Hop. Paris* 53(13/14): 837-831; 1977.

Intestinal bacterial flora was obtained by colonoscopy of 16 patients with chronic colonic disease. There were seven patients with functional colonic disorders and nine patients with mucous lesions such as rectal polyps, hemorrhoidal rectorrhagia, sigmoid diverticulosis, Hodgkin's disease, Crohn's disease, and hemorrhagic rectocolitis. No one bacteria was identified with any one disease, because the most seriously affected patients had varied bacteria. Overall, 750 bacterial strains were found and some *Candida* strains. Patients with irritable bowel syndrome had a predominance of proteolytic *Pseudomona*. The patient with Hodgkin's disease had an abundance of *Streptococcus faecalis* associated with *S. aureus* and five species of *Pseudomonadas*. One patient with rectorrhagia had at least 10 species of the latter strain. None of the patients were on antibiotic therapy. No bacterial sensitivity study was done due to the mass of bacteria isolated and identified.

4148 HUMAN RECTAL MUCOSA: PROCTOSCOPIC AND MORPHOLOGICAL CHANGES CAUSED BY LAXATIVES. (Eng.) Meisel, J. L.; Bergman, D.; Graney, D.; Saunders, D. R.; Rubin, C. E. (Univ. Washington Sch. Medicine, Seattle, WA 98195). *Gastroenterology* 72(6):1274-1279; 1977.

To determine whether laxatives alter the proctoscopic and morphological appearances of the human rectum, 10 normal subjects were studied prospectively, and the following manipulations were assessed in a randomized, blinded manner: no treatment, oral mannitol to induce diarrhea, isotonic saline enema, Fleet's Phospho-Soda enema, and bisacodyl (10 mg) by enema or suppository. Proctoscopy was carried out within 10 min after defecation of each test substance. The rectal mucosa after mannitol-induced diarrhea, or after saline enema could not be distinguished from untreated rectum by proctoscopy, light microscopy, or scanning electron microscopy. Fleet's enema and bisacodyl invariably changed proctoscopic appearances and frequently altered light and scanning microscopic aspects. Both Fleet's enema and bisacodyl caused sloughing of surface epithelium. In addition, light microscopy revealed that bisacodyl decreased the uptake of hematoxylin and eosin by crypt epithelial cells in 16 of 25 cases, so that the affected cells had a partially erased appearance. The lamina propria of 3 of these 25 biopsies contained polymorphonuclear cells. Transmission electron microscopy revealed that the abnormal crypt epithelial cells contained fewer cytoplasmic organelles and less nuclear chromatin. All lesions resolved within 7 days. Fleet's enema and bisacodyl by rectum may mislead the proctologist and the pathologist by altering normal rectal mucosa.

4149 RECTAL WALL BLEEDING--AN OVERLOOKED SOURCE OF MASSIVE LOWER GASTROINTESTINAL HEMORRHAGE. (Eng.) Thomson, J. G.; Gold, R. E.; Grace, D. M.; Passi, R. B. (Univ. Hosp., London, Ontario N6G 2K3, Canada). *J. Can. Assoc. Radiol.* 28(2): 142-145; 1977.

Two cases of rectal bleeding are presented in which the diagnosis was made angiographically. In the first patient, a 59-yr-old woman, sigmoidoscopy demonstrated bleeding above 25 cm. Angiography of the inferior mesenteric artery from the upper rectum to the splenic flexure showed several areas of aneurysm dilatation in the middle colic artery, but the bleeding site was not seen. Subsequent arteriography of the superior mesenteric artery also showed no bleeding site. A further inferior mesenteric arteriogram that had been unintentionally lower revealed the bleeding site 3 cm proximal to the mucocutaneous junction. In the second patient, a 41-yr-old woman, sigmoidoscopy demonstrated no lesion, but blood was seen coming from above 20 cm. Arteriography was performed, and care was taken to include the entire anorectal region on the films despite the sigmoidoscopic findings. Selective inferior mesenteric artery injection showed that the bleeding site was about 4 cm above the mucocutaneous junction. As in the first patient, the site of hemorrhage was a branch of the left superior rectal artery. Care must be taken to include the entire rectum on films obtained during inferior mesenteric artery injection, regardless of the sigmoidoscopic findings.

4150 ARTERIAL EMBOLIZATION IN THE TREATMENT OF MASSIVE GASTROINTESTINAL HEMORRHAGE: USE IN A CASE OF PERSISTENT RECTAL BLEEDING FOLLOWING RECTAL POLYPECTOMY. (Fre.) Franck, P.; Tongio, J.; Wenger, J. J.; Cinqualbre, J.; Dupeyron, J. P. (No affiliation given). *Chirurgie* 103(2):45-50; 1977.

Arterial embolization was used in the treatment of rectal bleeding in a 30-yr-old man following rectal polypectomy. Initially the patient presented with rectorrhagia, liquid diarrhea, fever, and weight loss. Rectoscopy and barium enema revealed diffuse generalized rectocolic polyposis. Biopsies confirmed benign adenomatous polyps and the patient underwent total colectomy. A later polypectomy of the rectum was followed by massive rectal bleeding. Selective arteriography demonstrated the artery responsible for the bleeding, which stopped immediately after embolization with pieces of sponge mixed with Thrombase and the patient's blood. Control arteriography showed that the clots in the embolized artery as well as the extravasations had disappeared. Control rectoscopy after 1 month revealed normal rectal mucosa.

4151 BARIUM ENEMA, PROCTOSIGMOIDOSCOPY AND UPPER GASTROINTESTINAL SERIES IN THE PREOPERATIVE EVALUATION OF THE CANCER PATIENT. (Eng.) Bagley, D. H.; Felix, E. L.; Sindelar,

W. F.; Doppman, J. L.; Ketcham, A. S. (Yale Univ. Sch. Medicine, New Haven, CT 06437). *Cancer* 39(4): 1743-1747; 1977.

The findings on routine upper gastrointestinal series, barium enema, and proctosigmoidoscopy in 566 patients over a 5-yr period were reviewed to determine their value in the preoperative evaluation in cancer patients. Routine upper gastrointestinal series was performed in 453 patients, barium enemas in 490, and proctosigmoidoscopies in 342. No metastases or second primary malignancies were detected by the upper gastrointestinal series, but the extent of large intra-abdominal tumors were delineated. Barium enema and proctosigmoidoscopy together revealed three unsuspected primary colonic tumors (1.2% in patients over 50 yr of age). Sigmoidoscopy and examination of the stool for occult blood would have revealed the same patients. Barium enema may be limited to surgical cancer patients in whom the extent of local tumor invasion is to be defined and to older patients in whom colonic tumors are suspected. Neither upper gastrointestinal series nor barium enema appear to be of value as a routine preoperative screening test in surgical cancer patients.

4152 THE ROLE OF INTRACAVITARY IRRADIATION IN THE CURATIVE TREATMENT OF CARCINOMA OF THE RECTUM: 170 CASES.

(Fre.) Papillon, J. (12, quai du General Sarrail, F 69006 Lyon, France). *Nouv. Presse Med.* 6(4):250-254; 1977.

The results of the treatment of 170 cases of rectal cancer by intracavitary radiotherapy (contact radiotherapy and interstitial curietherapy) are presented. All patients had well-differentiated invasive adenocarcinomas. Contact radiotherapy was given in 2-min intervals over 4-6 weeks; curietherapy was usually given as adjunct therapy. Of the 170 patients, 126 survived 5 yr and were considered clinically cured of their cancer; 5 of these patients had surgery for local recurrences. Forty-four patients died, 19 of progression of the cancer, 22 of intercurrent disease, and 3 after surgery for adenopathy of the rectal sheath (1) and for falsely suspected scar formation. This ambulatory method of radiotherapy is safe and is recommended for patients who are elderly or whose condition is fragile.

4153 COLONIC TUMORS FOLLOWING URETEROSIDMOIDOSTOMY FOR EXSTROPHY OF THE BLADDER: CLINICAL AND ANATOMICAL STUDY OF TWO CASES.

(Fre.) Potet, F.; Weiss, A. M.; Soullard, J.; Cendron, J. (Hopital Beaujon, F 92110 Clichy, France). *Gastroenterol. Clin. Biol.* 1(1):59-65; 1977.

Two cases of colonic tumors arising in a man and woman approximately 25 yr after ureterosigmoidostomy for exstrophy of the bladder are presented. Exstrophy of the bladder was performed in the man at 7 yr of age; 25 yr later a biopsy obtained rectoscopically revealed an adenocarcinoma of the right ureter, which recurred on the left ureter 1 yr later. Two cystic polyps developed at the orifices of the ureters in a 34-yr-old woman, 25 yr after surgery for exstrophy. Anatomic pathological examination of the different lesions showed almost identical features. In the first case, two tumor lesions developed successively; in the second case, the two tumors developed simultaneously. Histologically, the tumors had the features of typical juvenile polyps. The entire polyp was comprised of cystic formations. The stroma was edematous, congestive, and infiltrated with inflammatory cells. Urologic and gastrointestinal follow-up are recommended in such patients.

4154 COLITIS IN CHILDREN WITH THE HEMOLYTIC-UREMIC SYNDROME.

(Eng.) Tochen, M. L.; Campbell, J. R. (Univ. Oregon Health Sciences Center, 3181 S. W. Sam Jackson Park Rd., Portland, OR 97201). *J. Pediatr. Surg.* 12(2):213-219; 1977.

The cases of four children with hemolytic-uremic syndrome in combination with colitis are presented. The patients (3 girls and 1 boy) ranged in age from 10 months to 3 yr. All four patients had bloody diarrhea which was associated in three cases with vomiting. The hemolytic-uremic syndrome was characterized by hemolytic anemia, renal failure, and thrombocytopenia. Submucosal hemorrhage with "thumbprinting" on roentgenographic examination of the colon with barium was demonstrated in all four patients, rectal prolapse in two patients, and pseudomembranous enterocolitis and toxic megacolon in one. A partial colectomy and temporary colostomy, hemodialysis, and kidney transplant were required in this latter patient. The presence of the described colonic symptoms in a child with bloody diarrhea should suggest hemolytic-uremic syndrome. Sigmoidoscopy and barium enema examination should be carried out in selected patients with this syndrome to evaluate the degree of colonic involvement and the need for surgery.

4155 RADIOLOGICAL ASPECTS OF ISCHEMIC COLITIS. STUDY OF EIGHT CASES.

(Fre.) Benacerraf, R.; Delage, Y.; Blery, M.; Bismuth, V. (Service de radiologie, Hopital Louis Mourier, 178 rue de Renouilliers, 92700 Colombes, France). *Ann. Radiol. (Paris)* 19(5):495-504; 1976.

The radiological aspects of ischemic colitis in eight patients are presented. Two patients died of advanced disease. One had total necrotic ischemia of the rectosigmoid and died 1 month after surgery following an occlusion syndrome associated with stenosis of the left colon. Autopsy revealed vast hemorrhagic ulcerations of the entire rectum. The other died of mesenteric infarction associated with lesions of the small intestine and right colon. Clinically, five patients presented with bloody diarrhea and abdominal pain; one patient also had an occlusion plus a perforation. Radiologically, two patients showed gaseous distension of the small intestine. Barium enema revealed four localizations at the left colic angle, two at the rectosigmoid, and one at the sigmoid only; in one patient, the right colon and the end of small intestine were involved.

Ulcerations were also evident in three of eight patients, and tubular stricture of the colon was seen by barium enema in four. Arteriography did not present much information, but it did reveal vascularization, preferentially of the internal part of the colon wall next to the lumen in two patients. The diagnosis of ischemic colitis was established on the basis of the coincidence of several factors: age, vascularization, abdominal pain, rectorrhagea, radiological signs, the anatomopathological examination in four cases, and the evolution of the disease.

4156 RECTOPLASTY WITH POSTERIOR TRIANGULAR COLONIC FLAP--A RADICAL NEW OPERATION FOR HIRSCHSPRUNG'S DISEASE. (Eng.) Kasai, M.; Suzuki, H.; O'hi, R.; O'htomo, S. (Tohoku Univ. Sch. Medicine, 1-1, Seiryo-Cho, Sendai, Japan). *J. Pediatr. Surg.* 12(2):207-211; 1977.

Rectoplasty with a posterior triangular colonic flap was carried out in 15 patients with Hirschsprung's disease; this procedure was developed to eliminate the anastomotic leakage sometimes encountered in rectal myotomy with colectomy. The posterior wall of the rectum is split in the midline, and both angles are trimmed off. The colon is divided at the level where it has been demonstrated to have normal ganglion cells, and is split along its taenia libera and both angles are cut off to make a triangular flap. The incision of the posterior wall of the rectum is extended through the dentate line, cutting the upper half of the internal sphincter, and the triangular colonic flap is pulled down through the rectum and colorectal anastomosis is started from below. The patients ranged from 3 months to 10 yr, and follow-up after this procedure ranged from 2 months to 7 yr. The clinical evaluation of bowel habit was excellent in 12 patients, fair in 1 (occasional incontinence), and poor in 1. The remaining patient was too young for assessment of continence. Rectal sensation was satisfactory in 12 of 14 patients older than 2 yr. Postoperative manometric studies revealed a positive rectoanal reflex in 9 of 11 patients; recto-anal reflex was negative in the remaining 2 cases that were assessed as fair or poor in bowel habit.

4157 SEROLOGIC DETECTION OF PERSONS AT RISK IN FAMILIAL POLYPOSIS COLI. (Eng.) Vargish, T.; Dawkins, H. G., Jr.; Heise, E.; Myers, R. T. (Bowman Gray Sch. Medicine, Wake Forest Univ., Winston-Salem, NC). *Surg. Forum* 26:403-405; 1975.

Attempts were made to identify members at risk in a 47-member family in which at least seven members have polyposis coli. Thirty-nine members are living. Eight members had carcinoma with polyposis, three had carcinoma with presumed polyposis, and four had polyposis alone. ABO blood groups and HL-A genotypes were determined in 28 members and eight spouses; carcinoembryonic antigen (CEA) levels were determined in 26 members. Seven members with polyposis carry the same HL-A haplotype (11-W5); this haplotype is presumed (on the basis of HL-A studies of their children) in three members who died of colonic cancer. The 11-W5 haplotype is present in three members examined clinically and found free of disease, and in five members not yet clinically examined. One member with polyposis lacks this 11-W5 haplotype. There was no correlation between the presence of polyposis and ABO blood group antigens or CEA level. HL-A typing and genotype analysis of all members of a family may be useful in the identification of those potentially susceptible to familial polyposis coli.

4158 INDICATIONS FOR AND VALUE OF RADIOLOGIC EXAMINATION OF THE COLON. A STUDY OF EFFICACY. (Dan.) Reichardt, J.; Sparso, B. H.; Hegedus, V. (Glostrup Hosp., DK-2600 Glostrup, Denmark). *Ugeskr. Laeger* 138(42):2557-2561; 1976.

LARGE INTESTINE

Ulcerative Colitis

4199 TRYPTIC ENZYMES IN THE DIFFERENTIAL DIAGNOSIS OF INFLAMMATORY DISEASES OF THE COLON. (Ger.) May, H.; Gries, G. (Diakonissenanstalt, Hessstrasse 22, D-8000 Munich 40, W. Germany). *Munch. Med. Wochenschr.* 119(5):155-158; 1977.

Inflammatory diseases of the colon in 523 patients were differentiated by measuring the fecal excretion of chymotrypsin A (CA). The diseases included ulcerative colitis (137 patients), proctosigmoiditis (252), Crohn's disease (6), and diverse diseases of the gastrointestinal tract (128). Patients with ulcerative colitis excreted significantly more CA than patients with proctosigmoiditis. The mean CA concentration excreted by ulcerative colitis patients was about 800 µg/g of stool compared with 200 µg/g for proctosigmoiditis patients. CA excretion exceeded 500 µg/g in 6 patients with Crohn's disease, whereas 128 patients with gastrointestinal diseases had a mean CA excretion of 180 µg/g. The results indicate that inflammatory diseases of the colon can be differentiated by means of the chymotrypsin A excretion in the stool.

4200 PREGNANCY IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Ger.) Morl, M.; Rottler, H.; Hartwich, G. (Stoffwechselklinik der Landesversicherungsanstalt Wurttemberg, Bismarckstr. 31, 6990 Bad Mergentheim, W. Germany). *Dtsch. Med. Wochenschr.* 102(11):387-391; 1977.

The course of 20 pregnancies in 15 women with ulcerative colitis (UC) and 4 pregnancies in 15 comparable women with Crohn's disease (CD) over a 6-yr period is described. Two pregnancies in the UC patients were not evaluated due to lack of data. The disease did not affect the fertility rate of UC patients: 15 conceptions occurred during the inactive stage or remission of UC and 7 during acute attacks or chronic courses. Of the 20 UC pregnancies, normal deliveries occurred in 14, spontaneous abortions in 4, and therapeutic abortions were performed in 2 patients. The four spontaneous abortions occurred in patients with disease of the entire colon, and three of four had conceived during the acute stage. A normal pregnancy without complications occurred in 12/14 who conceived while the disease was latent or in remission. Therapeutic abortions should be considered when the disease and pregnancy begin simultaneously. Pregnancy did not change the symptomatology in 14/20 patients; the condition became worse in 6 and improved in 2 patients postpartum. No malformations were noted in the infants. Of the 15 women with CD who did not take contraceptive pills (12 with ileocolitis and 3 with terminal ileitis), 4 became pregnant (1/3 with terminal ileitis and 3/14 with ileocolitis). Fertility seems to be significantly reduced in CD patients with ileocolitis ($p<0.0005$) but not in those with terminal ileitis. A normal pregnancy can be expected after conception in the inactive period (2/4), whereas premature birth occurred in two women who conceived during the active phase of CD.

4201 CYTOMEGALOVIRUS INCLUSIONS IN PATIENTS WITH ULCERATIVE COLITIS AND TOXIC DILATION REQUIRING COLONIC RESECTION. (Eng.) Cooper, H. S.; Raffensperger, E. C.; Jonas, L.; Fitts, W. T., Jr. (Jefferson Medical Coll. Hosp., 11th and Walnut St., Philadelphia, PA 19107). *Gastroenterology* 72(6):1253-1256; 1977.

Six ulcerative colitis patients were studied whose colons contained intranuclear inclusions characteristic for cytomegalovirus (CMV). These cases were found during microscopic examination of 50 colon resection specimens from 46 patients with ulcerative colitis. All six patients were men, 47 yr of age or older, and all had marked severe and fulminating courses. Five patients had toxic dilation of the colon. Three patients had received no steroid therapy before their toxic dilation; however, all received steroids during attempts at medical management. Two other patients were found to have toxic dilation of the colon among the 46 patients, however, no evidence of CMV was found in these 2 cases. There were six patients without toxic dilation whose colon specimens showed destructive inflammation and granulation tissue extending into the muscularis propria or transmurally. None of the colons from these patients contained CMV inclusions. The finding of CMV may be coincidental in ulcerative colitis, but CMV may have played a role in altering the clinical course of the six patients in this study.

4202 THE LEUCOCYTE CHEMOTACTIC FUNCTION IN PATIENTS WITH ULCERATIVE COLITIS. (Eng.) Binder, V.; Riis, P. (Herlev Hosp., Univ. Copenhagen, DK 2730 Herlev, Denmark). *Scand. J. Gastroenterol.* 12(2):141-144; 1977.

The ability of neutrophilic granulocytes to react to a chemotactic stimulus was studied in 59 patients with ulcerative colitis in different stages of activity. Forty-one patients had active colitis, and the remaining patients had inactive disease (i.e., asymptomatic with a normal mucosa). Thirty-seven patients were untreated, while 21 received salazosulphapyridine (2-4 g daily), and 1 received prednisone enemas. The chemotactic response to casein of the WBC of the patients and of 25 controls was quantitated. WBC from the patients with ulcerative colitis showed a significantly lower chemotactic response index than WBC of normal controls (30.50 versus 15.15), and the index was lower in patients with active ulcerative colitis than in patients with inactive colitis (12.42 versus 21.37). There was no correlation between treatment and the chemotactic response.

4203 LYSOZYME IN PLASMA AND NEUTROPHILIC GRANULOCYTES IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Koldkjaer, O.; Klitgaard, N. A.; Schmidt, G. (Dept. Gastroenterology, Odense Univ. Hosp., DK-5000 Odense, Denmark). *Scand. J. Gastroenterol.* 12(2):135-140; 1977.

The lysozyme concentration in plasma (P) and in neutrophil WBC (N) was determined turbidimetrically in 32 patients with ulcerative colitis, 11 patients with Crohn's disease, 9 with hemorrhagic proctitis, and in 39 healthy controls. In the patients with ulcerative colitis, P increased 37% but N was reduced 30%. In patients with Crohn's disease and hemorrhagic proctitis, P and N were near normal. The high P in patients with ulcerative colitis reflects an accelerated destruction of neutrophil WBC as well as an increased turnover rate. The lowered N values may be due to inhibition of synthesis. The results suggest that lysozyme determination (N/P ratio) can be used in the differential diagnosis of active ulcerative colitis and Crohn's disease.

PANCREAS

4212 RATIONAL SEQUENCE OF TESTS FOR PANCREATIC FUNCTION. (Eng.) Mitchell, C. J.; Elias, E.; Agnew, J. E.; Summerfield, J.; Dick, R. (The Royal Free Hosp., London NW3 2QG, England). *Br. Med. J.* 2(6047):1307-1309; 1976.

^{75}Se-selenomethionine scanning and endoscopic retrograde pancreatography (ERP) were evaluated in relation to other pancreatic function tests to determine the most efficient combination of, or sequence of, tests for the routine clinical diagnosis of pancreatic disease. Of 144 patients with suspected pancreatic disease in whom a ^{75}Se-selenomethionine scan was performed, ERP was successful in 108 (75%). The final diagnosis was known in 100 patients. A normal scan reliably indicated a normal pancreas, but the scan was false-positive in 30%. ERP distinguished between carcinoma and chronic pancreatitis in 84% of cases but was false-positive in five patients with pancreatic disease. In extrahepatic biliary disease, both tests tended to give false-positive results. A sequence of tests to provide a rapid and reliable assessment of pancreatic function should be a radioisotope scan, followed by ERP (if the results of the scan are abnormal), and a Lundh test if the scan is abnormal but the findings on ERP are normal.

4213 FUNCTIONING CARCINOMA OF THE EXOCRINE PANCREAS, CASE REPORT AND REVIEW OF THE LITERATURE. (Ger.) Schreiber, D.; Probst, H. J. (Bezirkskrankenhauses, DDR-4021 Halle-Dolau, Rontgenstrasse, E. Germany). *Zentralbl. Allg. Pathol.* 121 (1/2):114-121; 1977.

A rare case of a functioning carcinoma of the exocrine pancreas with liver metastases and subcutaneous fat necrosis in a 62-yr-old man is presented. Initially, the patient presented with hepatomegaly, dyspnea, cyanosis of the lips, swollen knee joints, edema of the lower limbs, and reddish-blue spots on the skin of the legs. X-ray of the abdomen showed a caudally displaced colon. The patient's condition deteriorated, and he died of circulatory failure with a clinical diagnosis of an undefined tumor of the epigastrium. Autopsy revealed a widespread greyish-white to greyish-red, necrotic tumor occupying almost all the pancreas. Marked ectasia with ventral and caudal displacement of the stomach and transverse colon were noted. In the liver, there were chestnut-sized metastases with fatty areas of the parenchyma. Marked splenomegaly with moderate chronic nonspecific epicarditis and general arteriosclerosis were apparent. Microscopy of the pancreatic tumor showed that the tumor cells were mostly cylindrical with eosinophilic cytoplasm. The skin showed marked panniculitis but no positive proof of tumor cells.

4214 HEPATIC MANIFESTATION OF MUCOVISCIDOSIS. (Ger.) Luftner, J.; Scheibner, K.; Wockel, W. (Institut Allgemeine Pathologie der Medizinischen Akademie, DDR-50 Erfurt, Nordhauser Strasse 74, E. Germany). *Zentralbl. Allg. Pathol.* 121(1/2):195-200; 1977.

Hepatic manifestations were found at autopsy in 3/25 children who died of mucoviscidosis. Pulmonary manifestations were the cause of death in 24 children and 1 child died of meconium peritonitis. Focal biliary fibrosis was noted in a 3-month-old boy and an 8-month-old girl. An enlarged yellow liver with a slight irregular or scarred surface was seen in both cases. Microscopy revealed markedly enlarged Glisson's capsules with rich collagenous connective tissue and newly formed bile ducts with a very wide lumen and PAS-positive material. Swollen hepatocytes and isolated liver cell necrosis were also seen, but no cholestasis or inflammatory changes. Multilobular biliary cirrhosis was detected in a 7.5-yr-old boy who had an enlarged yellow liver with widely scarred surface. Histological examination showed irregular fibrotic areas with unclear demarcations diffusely permeated by pseudobiliary ducts. Secondary rather than primary alterations of the liver are far more frequent in mucoviscidosis.

PANCREAS

Pancreatitis

4219 PANCREATIC ASCITES: REPORT OF 14 CASES. (Fre.) Gouerou, H.; Cerf, M.; Benhamou, G.; Leymarios, J.; Debray, C. (Chaire de Clinique des maladies de l'Appareil digestif, Service de Gastro-Enterologie A, Hopital Bichat, 170, boulevard Ney, F 75877 Paris Cedex 18, France). *Arch. Fr. Mal. App. Dig.* 65(6):433-442; 1976.

Of 400 cases of chronic or subacute pancreatitis, long-lasting pancreatic ascites with high amylase levels was found in 14 patients. Pancreatic ascites are a serious complication because of associated weight loss, severe hypoalbuminemia, and other manifestations such as pleural and pericardial effusions, peripheral s.c. cytosteatonecrosis, and thromboembolism. The ascitic fluid always showed high protein levels, and peritoneal amylase levels always exceeded plasma amylase levels. A poor prognosis is reflected by the high mortality rate: two of nine patients died after surgery (3 relapses in 1 case), and three of five patients died without undergoing surgery. The causative lesions were mainly pancreatic cysts or segmental necrosis, some of which communicated with the peritoneal cavity. Portal hypertension or lymphatic blockade did not appear to be a determining factor. Surgery, rather than conservative therapy, is indicated whenever pancreatic ascites supervenes during the course of chronic pancreatitis.

4220 ULTRASONIC FEATURES OF ACUTE PANCREATITIS. STUDY OF 49 PATIENTS EXAMINED IN REAL TIME AND WITH GREY SCALE. (Fre.) Weill, F.; Bourgoin, A.; Eisenscher, A.; Gillet, M. (Service de Radiologie Centrale, Departement de Diagnostic, C.H.U., 2, place Saint-Jacques, F 25000 Besancon, France). *Arch. Fr. Mal. App. Dig.* 65(6):443-454; 1976.

Forty-nine patients suffering from acute pancreatitis (43 primary cases and 6 with chronic pancreatitis) were examined by echotomography in association with real time, the classic technique of "all or nothing," and with the grey scale technique. In two patients, the ultrasonic pictures revealed highly reflectogenic echostructure (type I). The echostructure was of a transonic pseudo-liquid type in 9 patients (type II), nonhomogeneous in 29 (type III), and nonhomogeneous with liquid areas in 4 (type IV). Rapid regression of these features was not unusual, particularly for types II and III. In the six cases of acute pancreatitis complicating chronic pancreatitis, the findings were less characteristic. The authors conclude that tomography during episodes of acute abdominal pain can provide highly specific images unavailable by other conventional radiologic techniques.

4221 CAROLI'S DISEASE WITH ACUTE PANCREATITIS AND ANGIOCOLITIS: DIAGNOSTIC AND THERAPEUTIC VALUE OF BILIARY DUCT ENDOSCOPY. (Fre.) Sahel, J.; Bourry, J.; Sarles, H. (Hopital Ste Marguerite, 270, Sainte Marguerite, F 13274 Marseille Cedex 2, France). *Nouv. Presse Med.* 5(32):2067-2069; 1976.

The use of retrograde endoscopic catheterization of the bile ducts was evaluated in a 65-yr-old woman with Caroli's disease associated with acute pancreatitis and angiocolitis. Initially the patient presented with intense epigastric pain and vomiting. Radiography with i.v. contrast media showed exclusion of bile ducts, and a gastroduodenal transit study indicated a diverticulum of the second segment of the duodenum. Moderate dilation of the extrahepatic bile ducts particularly of the intrahepatic branches with numerous cystic distentions was confirmed by endoscopic choledochowirsungography. During the examination, gentamycin (1 mg/ml) was mixed with the contrast medium. At follow-up, the patient was in excellent condition and the 10-day-old fever had abated. At a 16-month follow-up, no painful or angiocolitic symptoms were noted.

4222 ENTEROVIRUS INFECTIONS IN ACUTE PANCREATITIS--A POSSIBLE ETIOLOGICAL CONNECTION. (Eng.) Arnesjo, B.; Eden, T.; Ihse, I.; Nordenfelt, E.; Ursing, B. (Dept. Bacteriology, Univ. Lund, Lund, Sweden). *Scand. J. Gastroenterol.* 11(7):645-649; 1976.

A prospective study of 91 patients with confirmed acute pancreatitis screened from 142 patients seen over a 1-yr period with a preliminary diagnosis of this disease is presented. Several etiological factors of possible importance were tabulated: cholelithiasis (49 patients), alcohol (14 patients), trauma (5 patients), enterovirus (8 patients), mycoplasma (1 patient); 11 cases were classed as idiopathic, and in 3 cases, the etiological factors were not looked for. In the eight cases in which viral etiology was identified, the criteria used were isolation of enterovirus from the patients and evidence of significant titer rise against the viral type isolated. The viral agents identified were Coxsackie viruses B2, B3, and B5 and ECHO viruses 6, 11, 22, and 30. In 10 other patients, evidence of enterovirus infection was found, but there was no titer rise of neutralizing antibodies. The rate of isolation of enteroviruses in the population having acute pancreatitis was 18 of 91, as compared with the rate among a general population screened at the same period, which was 3% of 984.

4223 COLON STENOSIS AFTER PANCREATITIS. (Ger.) Lankisch, P. G.; Lopez, E.; Winckler, K.; Schuster, R. (Medizinische Universitatsklinik, Humboldtallee 1, D-3400 Gottingen, W. Germany). *Schweiz. Med. Wochenschr.* 106(37):1243-1247; 1976.

Barium enema revealed partial colonic stenosis at the splenic flexure in 5/35 patients with acute (2), acute relapsing (1), or chronic pancreatitis (2). A subsequent laparotomy in three of five patients showed colonic perforation with retroperitoneal abscess, adhesions between the colon and pancreas, and marked pancreatic edema, resp. These patients complained of bloody stools. A barium enema follow-up 3 and 6 months later revealed spontaneous resolution of the stenosis in two patients. A review of the literature showed that in 35 other cases, colonic stenosis after pancreatitis was usually incomplete, located at the splenic flexure, and due to adhesions between the colon and pancreas. Of these 35 patients, 2 underwent conservative therapy and 31 underwent laparotomy; resection of the pancreas and colon was performed in 18/31. Two other patients died during surgery. Evaluation of the total 40 cases suggests that the extent and development of partial or complete colonic stenosis after pancreatitis are independent of the age of the patient or the etiology and severity of the pancreatitis.

4224 SERUM ISOAMYLASES IN CHRONIC PANCREATITIS. (Eng.) Skude, G.; Eriksson, S. (Malmo General Hosp., S-214 01 Malmo, Sweden). *Scand. J. Gastroenterol.* 11(5):525-527; 1976.

Serum isoamylases were quantitated separately in 15 patients with chronic pancreatitis as an index to pancreatic exocrine function. The isoamylases were separated and measured by agarose electrophoresis. In 156 healthy controls, the range of variation of pancreatic isoamylase activity was 45-175 U/l (mean=88 U/l). All 15 patients with chronic pancreatitis had values lower than 2 standard deviations below the normal mean. The complete absence of pancreatic isoamylase was noted in eight patients, resulting in a mean value of 7 U/l for all the patients. The mean salivary isoamylase activity was 82 U/l in the normal controls and 124 U/l in the patients ($p<0.01$). Determination of the serum pancreatic isoamylase is a simple screening procedure that should be useful in the diagnosis of exocrine pancreatic insufficiency.

4225 COMPARATIVE ASSESSMENT OF DIAGNOSTIC TESTS IN PANCREONECROSIS. (Rus.) Vladimirov, V. G.; Sergienko, V. I.; Farkhutdinov, R. R.; Zhuravlev, A. G. (Dept. Surgery, N. I. Pirogov Second Moscow Medical Inst., Moscow, USSR). *Klin. Med. (Mosk.)* 54(10):85-90; 1976.

4226 AMYLASE CLEARANCE IN RELATION TO CREATININE CLEARANCE IN THE DIAGNOSIS OF ACUTE PANCREATITIS. (Fre.) Hostein, J.; Fournet, J.; Morel, F.; Denis, M. C.; Bonnet-Eymard, J. (Centre Hospitalier Regional et Universitaire, F 38043 Grenoble Cedex, France). *Nouv. Presse Med.* 5(31):1979-1980; 1976.

LIVER AND BILIARY TRACT

4245 EXAMINATION OF HEPATOBILIARY FUNCTION USING A SCINTILLATION CAMERA AND ELECTRONIC DATA PROCESSING. (Ger.) Kuba, J.; Ullmann, V.; Kuchar, O.; Vavros, B.; Sajnar, J. (Nuklearmedizinische Abteilung des Bezirkskrankenhauses, Strasse Vitezneho unora 1790, 708 52 Ostrava, Czechoslovakia). *Nuklearmedizin* 15(2):63-70; 1976.

After i.v. administration of ^{131}I-BSP, hepatobiliary function was evaluated in 20 controls and in 70 patients with a suspicion of hepatobiliary disease by sequential scintigraphy (SS) using a scintillation camera. To verify the results, a liver biopsy was done in 49 patients with compensated and decompensated cirrhosis plus hyperbilirubinemia, chronic aggressive hepatitis, and total obstruction of the biliary tract. In the controls, radioactivity was detected after 20-30 min in the subhepatic region and after 40 min in the entire gallbladder; the transverse colon was visible after 24 hr. In patients with carcinoma of the head of the pancreas and obstructive jaundice, there was no passage of radioactivity into the intestines. Conversely, activity was detected after 3 or 24 hr in icteric patients with liver cirrhosis. The velocity coefficients obtained by computer ranged from 0.19 to 0.31 for the controls and from 0.06 to 0.19 for the patients. A liver abscess was detected in one patient, and malignant transformation was detected in seven. Comparison with the standard BSP test demonstrated SS to be more sensitive.

4246 MARKED DELAY IN INDOCYANINE GREEN PLASMA CLEARANCE WITH A NEAR-NORMAL BROMOSULPHOPHTHALEIN RETENTION TEST: A CONSTITUTIONAL ABNORMALITY? (Eng.) Okuda, K.; Ohkubo, H.; Musha, H.; Kotoda, K.; Abe, H.; Tanikawa, K. (First Dept. Medicine, Chiba Univ. Sch. Medicine, Chiba, Japan). *Gut* 17(8):588-594; 1976.

The cases of five patients showing a normal BSP and a marked delay in indocyanine green (ICG) plasma clearance and two patients' families with clustering of the same abnormality are described. Two patients had Gilbert's syndrome (patient 1 and 2), one (patient 4) had an acute hepatitis B surface antigen (HBsAg)-negative hepatitis, and the other two (patient 3, cervical lymphadenitis; patient 5, prostate carcinoma) had no detectable liver abnormality. Plasma disappearance curves for ICG declined linearly after i.v. administration of 0.5 mg/kg ICG or 5 mg/kg BSP under fasting conditions. Retention of BSP at 45 min was 4.9%, and retention of ICG at 15 min was 67.3% (case I). Marked reduction in hepatic uptake, storage capacity, and biliary transport maximum was reported in patients 1, 2, and 3. Patients and controls showed similar ICG distribution and amount bound per unit protein. No consanguinity was demonstrated in the two families and pedigrees (patients 4 and 5) studied. Incidence of disparity between marked ICG retention and normal BSP test is very high among patients with Gilbert's syndrome (2 of 8), compared to controls (3 of 1,000). No selective BSP abnormality in the face of normal ICG test was reported in 200 patients. A preliminary defect in the transport of ICG by hepatocytes is suggested.

4247 CHARACTERISTIC ALTERATIONS OF SERUM ISOENZYMES OF AMYLASE IN DISEASES OF LIVER, PANCREAS, SALIVARY GLAND, LUNG, AND GENITALIA. (Eng.) Warshaw, A. L.; Kang-Hyun, L. (Harvard Medical Sch., Boston, MA 02114). *J. Surg. Res.* 22(4):362-369; 1977.

Serum amylases were analyzed by electrophoresis and isoelectric focusing in sera from 30 normal subjects and 61 patients with diseases associated with hyperamylasemia (common bile duct obstruction without pancreatitis, 20; pancreatic carcinoma, 5; salivary gland trauma, 5; acute and chronic liver disease, 14; macroamylasemia, 5; and various other disorders, 12). Electrophoresis of normal serum revealed two major peaks of amylase activity; one corresponding to pancreatic (P1) and one to salivary (S1) isoamylases. Two to four minor peaks were also present in normal serum, and a slower-moving amylase, found to increase in liver disease, was detected in small quantities in sera from 20% of normal subjects. Isofocusing of normal serum showed four definite peaks of amylase activity.

Serum from patients demonstrated all the electrophoretic peaks of amylase activity observed in normal serum; however, one or more peaks may be elevated and new peaks may appear. Electrophoretic patterns for various diseases are described. Similarly isoelectric focusing of serum from patients with hyperamylasemia revealed characteristic patterns permitting identification of the source of the amylase isoenzymes. Analysis of serum by electrophoretic and isoelectric technique is clinically useful when the cause of hyperamylasemia is uncertain.

4248 THE PEROXISOMES OF HUMAN HEPATOCYTES. (Eng.) Sternlieb, I.; Quintina, N. (Div. Genetic Medicine, Dept. Medicine, Albert Einstein Coll. Medicine, Bronx, NY 10461). *Lab. Invest.* 36(2):140-149; 1977.

The peroxisomes of 16 patients with various liver diseases and 4 normal subjects were studied in electron micrographs of liver biopsy specimens. In most of the pathologic hepatocytes, peroxisomes exhibited an increase or decrease in size or numbers when compared to controls and/or alterations of the consistency of the matrix, abnormal clustering, and the appearance of electron-dense inclusions. Some of these abnormalities were reversible in three patients with Wilson's disease treated with D-penicillamine. Although no specific pattern of morphologic alterations of peroxisomes could be correlated with any particular disease, the abnormalities were consistent with a role of these organelles in lipid metabolism.

4249 AN INTERPRETATION OF THE SERUM ALKALINE PHOSPHATASE ISOENZYME PATTERNS IN PATIENTS WITH OBSTRUCTIVE LIVER DISEASE. (Eng.) Price, C. P.; Sammons, H. G. (Southampton General Hosp., Southampton, England). *J. Clin. Pathol.* 29(11):976-980; 1976.

To examine the theory that biliary obstruction leads to an increase of alkaline phosphatase isoenzymes in the circulation together with regurgitation of bile alkaline phosphatase isoenzyme, the isoenzyme patterns of 194 patients with proven hepatobiliary disease were studied. The patients included 37 with extrahepatic obstruction, 14 with hepatic metastatic carcinoma with jaundice, 42 with carcinoma without jaundice, 24 with viral hepatitis, and 77 with other hepatic disorders; 19 patients with skeletal disorders were also included. The serum alkaline phosphatase isoenzyme patterns were similar in all patients with liver disease. The isoenzyme with an electrophoretic mobility similar to that of the liver isoenzyme and the isoenzyme remaining at the origin represented the main fractions present. The "origin" isoenzyme bore so many similarities to the main isoenzyme in human bile that it was designated the bile isoenzyme. It was found in 98% of all the patients with liver disease. The results support the theory that in biliary obstruction the increase in serum alkaline phosphatase is in part due to regurgitation of the biliary isoenzymes.

4250 CLINICAL SIGNIFICANCE OF SERUM PHOSPHOLIPIDS IN SOME HEPATOBILIARY SYSTEM DISORDERS. (Rus.) Frolkis, A. V.; Kondrachenko, O. V.; Abramzon, M. A. (Dept. Internal Medicine, Univ. Petrozavodsk, Petrozavodsk, USSR). *Sov. Med.* (5):101-105; 1976.

The clinical significance of blood serum phospholipids was studied in 111 patients with chronic disorders of the hepatobiliary system (27, liver cirrhosis; 45, chronic hepatitis; 6, active phase of chronic hepatitis; 7, fatty degeneration of the liver; and 26, cholelithiasis). Seven basic phospholipid fractions--cardiolipin, cephalin, lecithin, sphingomyelin, phosphatidylserin, phosphatidylinosite and lysolecithin--were analyzed by bidimensional chromatography on silica gel. In patients with liver cirrhosis or the active phase of chronic hepatitis, total phospholipids were decreased to 201.5 ± 7.0 mg% compared to 303.4 ± 24.0 mg% in controls ($p<0.01$). In fatty degeneration, they increased to 381.9 ± 5.7 mg%. In cholelithiasis, they were essentially unchanged (340.3 ± 10.6 mg%, $p>0.5$). Phospholipids showed decreased lysolecithin ($p<0.01$) and sphingomyelin ($p<0.02$) levels with a relative rise in lecithin, phosphatidylserine, and phosphatidylinosite ($p<0.01$). In patients with chronic persistent hepatitis only phosphatidylserine and lysolecithin were changed essentially. In cholelithiasis, cephalin was decreased. In 17/27 patients with liver cirrhosis, in all active hepatitis patients, and in 12/45 chronic hepatitis patients, two additional ninhydrin-positive phospholipid fractions were encountered. Phospholipid fractions were investigated repeatedly in four patients with cirrhosis and in eight chronic hepatitis patients in clinical remission. In hepatitis, phospholipids, except for lysolecithin, tended to normalize. In cirrhosis, alterations of phospholipids were not seen, however, additional phospholipid fractions disappeared. Differences in the glutamic pyruvic transaminase activity were distinguished in cirrhosis and chronic hepatitis. These changes in the blood serum phospholipid fractions reflect pathological processes in the liver. The appearance of additional phospholipid fractions is considered a sign of aggravation of the liver disease.

4251 GAMMA-GLUTAMYL TRANSPEPTIDASE LEVELS IN DISEASES OF THE LIVER AND BILE DUCTS. (Hun.) Varga, L.; Sohar, I.; Dobronte, Z. (I. Belgyogyaszati Klinika, Szegedi Orvostudomanyi Egyetem, Szeged, Hungary). *Orv. Hetil.* 117(4):201-203; 1976.

Serum γ-glutamyl transpeptidase (GGT) levels were determined in 133 patients with various hepatic and biliary diseases and compared with other enzyme activities. Sera from 23 subjects with intact liver were used for control. The GGT levels (in U/l) were 286 ± 46 in patients with intrahepatic tumor metastases, 95 ± 17 in liver cirrhosis, 161 ± 51 in cholangiohepatitis, 301 ± 43 in hepatic bile duct obstruction, 80 ± 13 in alcoholic liver diseases (chronic alcoholic hepatitis and liver cirrhosis), and 18 ± 3 in nonalcoholic fatty liver degeneration; the control value was 16 ± 2. Consequently, the GGT levels were significantly higher than in the controls in all groups, except for patients with fatty liver. The alkaline phosphatase activity was similarly increased in patients with biliary tract obstruction, intrahepatic tumor metastases, and cholangiohepatitis. The lactate dehydrogenase was significantly increased in tumor patients only. The glutamic-pyruvic transaminase and glutamic-oxaloacetic transaminase levels were increased mainly in patients with liver cirrhosis and biliary tract obstruction. The findings indicate that the GGT test is a more sensitive diagnostic tool than any of the other enzymes investigated.

4252 ANTIBODY ACTIVITY IN SOME CHRONIC LIVER DISEASES. (Cze.) Macak, J. (Katedra patologie lekarske fakulty University Palackeho, 775 00 Olomouc, Jilova 25, Czechoslovakia). *Cas. Lek. Cesk.* 115(48):1483-1486; 1976.

Twenty patients with cholestasis, 27 with liver cirrhosis of other than biliary etiology, and 19 with chronic hepatitis and other chronic liver diseases were studied. To determine the occurrence of antimitochondrial, smooth muscle, and antinuclear antibodies (AMA, SMA and ANA, resp.), the Coons immunofluorescence technique, using fresh or freeze-thawed sera and human or rat organs, was used. In the first group, all eight cases of primary biliary cirrhosis gave positive results for AMA, while two of them gave positive SMA results. Of the five patients with extrahepatic cholestasis, AMA was present in two, and SMA in one. Two of these had secondary biliary cirrhosis. In the second group, AMA was present in eight patients, and SMA was present in four patients, most of them with cryptogenic liver cirrhosis (AMA in four, SMA in two) or postviral hepatitis liver cirrhosis (AMA in two). The presence of AMA and SMA in one Wilson's disease patient was unusual. All three patients with lupoid hepatitis had AMA, with responses varying, depending on the antigenic substrate. In the third group, AMA were detected in one case of chronic alcoholism with liver fibrosis and steatosis, one case of porphyria cutanea tarda, and one unclear case identified at autopsy as venulo-occlusive disease. Results indicate a definite difference between the AMA pictures in acute liver diseases and primary biliary cholestasis. These tests should be useful in the further clarification of autoimmune diseases.

4253 TREATMENT OF CHRONIC LIVER DISEASES. (Ger.) Moller, E.; Schmitt, R. (Evangelisches Krankenhaus, Innere Abteilung, D-6702 Bad Durkheim, W. Germany). *Med. Klin.* 71(43):1831-1835; 1976.

The results of treating 89 chronic liver disease patients with combined i.v. and p.o. thioctic acid (TA) are reported. The diseases included chronic hepatitis (42), hepatic cirrhosis (25), protracted hepatitis (14), and alcohol-toxic adiposis hepatica, stage II (8). The average age of the patients was 43.9 yr. Patients were started on TA (50 mg b.i.d. i.v.) while hospitalized (4-6 weeks) and then put on TA (two 50-mg tablets t.i.d.) for an average of 3 months on an outpatient basis. Responding patients showed a significant improvement in SGOT, SGPT, and α-glutamyltransferase, accompanied by histological improvement. Overall, liver function improved in 66 patients, remained unchanged in 12, and worsened in 11. A histological examination was performed in 44 patients: 36 patients showed improvement, 5 remained unchanged, and 3 worsened. Patients with posthepatic cirrhosis, chronic alcohol-toxic hepatitis, and alcohol-toxic adiposis hepatica had almost 100% histological improvement. One patient complained of difficulty in breathing, which was attributed to the fast injection rate of TA. No other side-effects were noted.

4254 THE DIAGNOSIS OF HEPATIC METASTASES BY ENZYME ESTIMATION. THE VALUE OF GAMMA-GLUTAMYLTRANSPEPTIDASE. (Fre.) Champault, G.; Garnier, M.; Patel, J. C. (35, rue Ampere, F 94400 Vitry-sur-Seine, France). *Nouv. Presse Med.* 6(19): 1635-1637; 1977.

Serum enzyme levels were determined in 50 patients (22 women, 28 men; average age, 65.2 yr) with various tumors, 25 of whom also had hepatic metastases (HMS). The tumor sites included colorectum (16 patients), stomach (10), pancreas (3), primary liver (2), esophagus (1), bladder (3), prostate (3), ovary (1), uterus (1), and breast (1). An additional six patients had liver metastases and undiagnosed primary site tumors. None of the patients had other hepatic, biliary, or pancreatic diseases. All the cancer patients with HMS had a marked elevation of gamma-glutamyltranspeptidase (GGT) with an average value of 287 IU for the 25 patients. Average values for the other enzymes were alkaline phosphatase (AP), 434 IU; SGOT, 58.8 IU; SGPT, 80.5 IU; and 5'-nucleotidase, 126 IU. The increase in GGT was correlated with the presence of HMS in 96% of the cases and was a better indicator of metastases than AP (84%), SGOT (72%), or SGPT (64%). Patients without HMS and controls showed no significant differences in levels of GGT, AP, SGOT, or SGPT. The results suggest that the measurement of GGT is an accurate diagnostic aid for HMS.

4255 MECHANISMS AND HISTOPATHOLOGICAL BASES OF THE DIFFERENT KINDS OF INTRAHEPATIC EXCRETORY CHOLESTASES. (Fre.) Albot, G.; Caulet, T.; Petit, J. (8, rue des Saints-Peres, 75007, Paris, France). *Ann. Gastroenterol. Hepatol. (Paris)* 13(1):9-63; 1977.

Excretory cholestases may be due to lesions of the biliary pole of the hepatocyte or of the intra- or extrahepatic biliary tract, in contrast to secretory cholestases, which are caused by obstacles to bile secretion. The histological findings and causal mechanisms of biliary necrosis, centrolobular obstruction, dilatation of cholangioles, and pseudobile ducts are discussed. Biological consequences, such as bilirubinemia and hypercholalemia, and their pathogenicity are explored. The causes and histopathological bases of the acute excretory cholestases in viral hepatitis are surveyed along with jaundice during pregnancy and iatrogenic icterus caused by steroids or phenothiazin derivatives. Finally, the different chronic intrahepatic cholestases of Hanot's disease are described, and their particular etiopathology is discussed.

4256 NOTES ON PRURITUS WITH OR WITHOUT ICTERUS IN SEVEN CASES OF BENIGN RECURRENT INTRAHEPATIC CHOLESTASIS DURING PREGNANCY. (Ita.) David, D.; Garda, E.; Serra, E.; Sanesi, A. (Ospedale Maria Vittoria, Turin, Italy). *Minerva Gastroenterol.* 21(3):139-154; 1975.

Clinical data are reported in seven cases of benign recurrent intrahepatic cholestasis during pregnancy. All patients (27-36 yr old, in the 5th-8th month of pregnancy) manifested pruritus symptoms associated with cholestatic jaundice (5) or subicteric condition of the sclera (1); no jaundice was present in one patient. Glucuronates and nicotinamide, i.v., and cortisone induced decrease or disappearance of the pruritus symptoms, which recurred after treatment. Cholestyramine resin administered to one patient had a moderate antipruritic effect; there were no side-effects. Six of the patients had normal pregnancy and birth, while one gave premature birth (8th month) to a dead fetus (6 months old). The pathogenesis of the pruritus symptoms, with or without jaundice, may be attributed to the high hormone levels, rather than attributed to the high hormone levels, rather than to disturbances in the bilirubin uptake, or to diminution of the enzymatic activity required for bilirubin conjugation. The hormone overload may be responsible for alterations in the excretion mechanism of bilirubin. Since the hormone levels determined in these seven patients were discrepant and confusing (the pregnanediol was very high in one, same as in normal pregnancy in five, and lower than normal in one, while the estriol was normal in three and lower than normal in four), it is also suggested that the pathogenesis may be due to hormonal metabolites that are not usually present in pregnancy.

4257 PORTAL HYPERTENSION DUE TO CONGENITAL HEPATIC FIBROSIS. REPORT OF TEN CASES. (Por.) Okumura, M.; Shiroma, M.; Nakagawa, W. S.; do Canto, A. L.; Goncalves Borges, M. A.; Rosenbojn, J.; *et al.* (Depart. Clin. Medica, Fac. Medicina da Univ. de Sao Paulo, Sao Paulo, Brazil). *Rev. Hosp. Clin. Fac. Med. Sao Paulo* 31(3):166-173; 1976.

Diagnosis of congenital hepatic fibrosis was established in 10 patients (aged 11-33 yr) who underwent portosystemic by-pass for portal hypertension. Clinical manifestations, splenoportography, blood biochemistry, and macroscopic liver examination were recorded, and diagnosis was confirmed in each case by histological examination of liver biopsy tissue. Histopathology showed extensive fibrous connective tissue strands radiating from portal spaces and terminating abruptly in the middle of the lobules. Seven patients recovered satisfactorily after surgery, one never reported for follow-up study, and two patients died, one 14 days and the other 71 months after surgery.

4258 HYPEROXALURIA IN DISEASES OF THE LIVER AND INTESTINES. (Ger.) Ruge, W.; Kohler, J.; Fromm, H.; Schindler, D.; Canzler, H. (Med. Klinik, Med. Hochschule, D-3000 Hannover, W. Germany). *Z. Gastroenterol.* 15(1):45-55; 1977.

Urinary oxalic acid was measured in 24-hr urine specimens by the method of Hodgkinson and Williams in 28 controls and in 97 patients with gastrointestinal diseases. Increased excretion of oxalic acid was found in patients with indigenous sprue (11 cases, including 5 on gluten-free diets), malabsorption syndrome (10), chronic pancreatitis (8), liver cirrhosis (10), Crohn's disease of the small intestine (12), resection of the small intestine (7) or of the small and large intestine (12), proctocolectomy (1), and Whipple's operation (1). Increases in urinary oxalic acid in acute pancreatitis or after partial resection of the small intestine (on bulk-free diet), partial resection of the large intestine, and the Billroth II operation were not statistically significant. Four patients had urinary calculi after resection of the small intestine or part of the pancreas. Reduction of fat content and bulk in the diet reduced the oxalate excretion. Hyperoxaluria correlated with fat elimination in the stools, $^{14}CO_2$-excretion in the expired air determined by the glycocholate breathing test, the vitamin B_{12} resorption test, and with the length of the resected portion of the intestines. Hyperoxaluria is due to increased absorption of oxalic acid from the diet. Its mechanism is not clear but failure of fat resorption appears to be an important factor.

4259 GROWTH IN HEIGHT AND BONE AND ENDOCRINE ABNORMALITIES IN 11 CASES OF HYPOPLASIA OF THE INTRAHEPATIC BILE DUCTS. (Fre.) Courtecuisse, V.; Dommergues, J. P.; Girard, F.; Limal, J. M. (Service de Pediatrie, Hopital Antoine-Beclere, 157, rue de la Porte-de-Trivaux, F 92140 Clamart, France). *Sem. Hop. Paris* 23(8/9):525-531; 1976.

Growth and bone and endocrine abnormalities were studied in 11 children with hypoplasia of the intrahepatic bile ducts associated with mental retardation (10), facies (9), and cardiovascular abnormalities (11). Six children had delayed body growth, five had major nonfusion vertebral anomalies, and two showed a rudimentary spondyloschisis. Distinct bilateral coxa valga was seen seven times. Other anomalies included bony transparencies. One patient had a low level of protein-bound iodine, and somatotropin function was abnormal in five of eight children, with a prolonged rise in plasma somatotropin levels during arginine or ornithine stimulation. The testicular index was low in six boys; testicular biopsy in four showed interstitial fibrosis, alone or associated with other abnormalities.

4260 EXPERIENCES WITH EXTRACORPOREAL PERFUSIONS WITH HETEROLOGOUS PIG LIVERS IN THE TREATMENT OF ACUTE LIVER INSUFFICIENCY. (Ger.) Keitel, R.; Otto, U.; Schwarzer, R.; Klotzer, B.; Mahnke, P. F.; Wegner, H.; *et al.* (Chirurgische Klinik des Bereichs Medizin der Karl-Marx-Universitat, Liebigstrasse 20, DDR-701 Leipzig, E. Germany). *Dtsch. Gesundheitsw.* 32(5):216-219; 1977.

Six extracorporeal perfusions with heterologous pig liver were performed in four patients with liver failure due to endocarditis (1), ammonium bichromate intoxication (1), and viral hepatitis (2). The duration of the perfusions ranged from 225 to 2,330 min. The liver was kept in a perfusion liquid consisting of an electrolyte solution (pH 7.4) containing heparin, procaine, and sodium bicarbonate. The perfusion was done via the superficial femoral artery and the great saphenous vein. It was stopped in one patient after 4 hr because of an outflow obstruction that resulted in capsule distension ruptures and bleeding. The livers showed their normal dark-red color during the entire perfusion periods. They produced bile, and the bilirubin values of the collected bile were definitely higher than the serum bilirubin values, which dropped within the first 60 min after the end of perfusion in each case. A drop in peripheral WBC count was detected shortly after the start of three perfusions. One patient developed an acute immune reaction that was controlled with prednisone. Overall, the patients tolerated the perfusions well, but they died 11 hr to 5 days after the end of treatment.

4261 ULTRASTRUCTURAL STUDY OF THE LIVER IN TWO CASES OF HEREDITARY TYROSINEMIA. (Fre.) Scotto, J. M.; Stralin, H. G.; Landrieu, P. (INSERM Universite Paris-Sud, Hopital d'Enfants, 94270 Le Kremlin-Bicetre, France). *Gastroenterol. Clin. Biol.* 1(2):139-149; 1977.

Two patients (a male and a female, 3 months old) whose parents were not consanguine, both showing Debre-Fanconi tubulopathy, hepatomegaly, and significant increases in serum alkaline phosphatase were diagnosed as having hereditary tyrosinemia. Low levels of prothrombin-complex factors were noted and serum alpha-fetoprotein (AFP) levels were elevated (>10 mg%). Ion exchange chromatography values of serum tyrosine and methionine were elevated (4 and 10 mg%, resp.); phenylalanine levels were normal (0.8-1.3 mg%). Hepatic parahydroxyphenylpyruvate oxidase activity was low (30% of normal). A tyrosine and phenylalanine poor regimen resulted in lowered tyrosine and methionine serum levels and amelioration of the tubulopathy, but did not alter AFP or coagulation factor levels. Both patients died after 6 months of life. Liver ultrastructure was similar in both cases; two cellular types were identified. The most frequent were well differentiated hepatocytes; the other type was smaller, had few cytoplasmic organelles, and was located chiefly at the periphery of hepatic trabeculae. Nuclear abnormalities, particularly nucleoar hypertrophy, proliferation of rough endoplasmic reticulum (RER), and the presence of cytosomes represented the most striking changes in differentiated hepatocytes. Changes similar to those observed in the experimental effect of ethionine or methionine diet overload (i.e., ATP depletion in the liver) were noted and are in agreement with the action of hypermethioninemia in tyrosinosis. Proliferation of RER may be due to an increased synthesis of a structural protein (perhaps AFP). In this case, abnormal but differentiated hepatocytes may be the site of AFP synthesis, and it is postulated that hepatocytes have a neoplastic behavior in advance of a malignant tumor appearance.

4262 REACTIONS OF D-PENICILLAMINE WITH COPPER IN WILSON'S DISEASE. (Eng.) Rupp, H.; Weser, U. (Physiologisch-chemisches Institut der Universitat, Hoppe-Seyler-Strasse 1, D-7400 Tubingen, W. Germany). *Biochem. Biophys. Res. Commun.* 72(1):223-229; 1976.

The mode of chelation of copper with D-penicillamine, a drug used in treatment of Wilson's disease, was determined by x-ray photoelectron spectroscopy. Wilson's disease is characterized by a continued production of copper-binding proteins in the liver, whereas these proteins are produced only neonatally in healthy individuals. The overproduction results in high concentrations of copper in the liver and other tissues, and abnormally low levels of blood ceruloplasmin. D-penicillamine was found to chelate with copper (Cu) in both of its oxidation states, Cu(I) and Cu(II), which increases the ability of penicillamine to bind copper regardless of the stage of the illness. Cu(II) was apparently mobilized by a reduction mechanism resulting in the complex RSSRCu(II). The formation of the complex $\frac{1}{n}[RSCu(I)]_n$ was most frequent and was shown to be successfully excreted in the urine of rabbits, with a yield of up to 39% of the i.v.-infused dose of D-penicillamine as the complex.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

4274 BROMOSULFOPHTHALEIN (BSP) HEPATIC CLEARANCE AND MORPHOLOGICAL ALTERATIONS IN ICTERIC CHOLESTATIC SYNDROME IN INFANCY. (Eng.) Neto, U. F.; Wehba, J.; Patricio, F. R.; Machado, N. (Rua Luiziania, 129 c/4. CEP. 04560, Sao Paulo, SP., Brazil). *Arq. Gastroenterol.* 13(4):265-271; 1976.

In 17 infants, age 6 days to 7 months, with the cholestatic icteric syndrome, hepatic function was evaluated by BSP clearance and liver morphology by percutaneous biopsy. Three types of graphs were obtained from the BSP clearance studies (5 mg/kg, injected i.v. in 30 sec): (1) curve associated with cholestasis and alterations in the hepatocytes, (2) curve associated with alterations in hepatocytes and minimal cholestasis, and (3) curve associated with slight alteration of hepatocytes and total bile duct obstruction. Liver function as evaluated by BSP clearance showed appreciable changes in the majority of the patients, and a direct relationship between the BSP clearance and morphological changes in the liver was observed in 88% of the patients.

4275 DUBIN-JOHNSON-SPRINZ SYNDROME: ASSOCIATION OF CONGENITAL HEMOLYTIC ANEMIA, CUTANEOUS PHOTOSENSITIVITY AND ABNORMAL PORPHYRIN METABOLISM. HUMAN VERSION OF THE MUTANT CORRIEDALE SHEEP? (Fre.) Heller, F.; Ninane, G.; Lebacq, E. G. (Rue Paul Pasteur, 42 B-7100 La Louviere, Belgium). *Acta Gastroenterol. Belg.* 40(1/2):77-85; 1977.

The case history of a woman with jaundice increasing through six pregnancies (a seventh pregnancy terminated in stillbirth) is presented. The patient had experienced abdominal pain and photosensitivity (dermal vesicles). Hepatosplenomegaly, microcytic anemia, hyperbilirubinemia, and an elevated alkaline phosphatase were noted at the time of the seventh pregnancy. A spontaneous amelioration was noted 2 weeks later: total bilirubin was between 2.2-4.6% (80% conjugated); alkaline phosphatase was 3.3 UB. However, prothrombin level was 70% (factors II, V, VII, and X were 60%, 45%, 70%, and 70%, resp.). BSP did not colorize the duodenal duct, and BSP serum levels increased progressively after a minimum value of 11% at 30 min. Laparoscopic liver biopsy was jet-black, and showed pigmented hepatocytes, moderate siderosis, and a megakaryocyte. Ultrastructurally, morphological changes in mitochondria were noted. Significant splenic sequestration was noted. Elevated levels of copro- and uroporphyrins were observed (secondary porphyrinurea). It is suggested that the Dubin-Johnson-Sprinz syndrome and beta-heterozygous thalassemia with concordant hypersplenism could account for the abnormal porphyrin metabolism found in this patient. The clinical picture observed in these associated syndromes is compared with that described in mutant Corriedale sheep.

4276 THE EFFECT OF PHENOBARBITAL ON PATIENTS WITH DUBIN-JOHNSON SYNDROME. (Eng.) Merdler, C.; Burke, M.; Shani, M.; Felner, S.; Lurie, I. (Dept. Medicine, Ichilov Medical Center, Tel Hashomer, Tel Aviv Univ., Tel Aviv, Israel). *Digestion* 14(5/6):394-399; 1976.

Eleven patients with Dubin-Johnson jaundice were treated with phenobarbital (100 mg, p.o., t.i.d. for 2 weeks); no other medications were given during this time. The side-effects observed were somnolence, which subsided after 2-3 days, and constipation, which affected only four patients. Total bilirubin concentrations decreased significantly ($p<0.01$) in all patients, from an average before treatment of 4.65 ± 0.9 mg/100 ml to 1.32 ± 0.81 mg/100 ml; direct bilirubin fell from an average of 3.6 mg/100 ml to 1.05 mg/100 ml ($p<0.05$); and indirect bilirubin also decreased. The ratio of direct to total bilirubin was not altered significantly; it changed from 0.78 ± 0.5 to 0.79 ± 0.4. The hepatic clearance of BSP after i.v. administration of a 5-mg/kg dose was not significantly enhanced at 45 min, but at 120 min, the enhancement was significant ($p<0.01$). Significant changes were not observed in SGOT, serum alkaline phosphatase, cholesterol, or plasma proteins. The BSP tolerance test demonstrates that Dubin-Johnson syndrome is caused by a defect in the excretory liver function. The study further demonstrates that phenobarbital can alter certain hepatic functions. More study is needed on icteric patients with Dubin-Johnson syndrome to determine the site of action of phenobarbital, its long-term effects, and its optimal effective dosage.

4277 JAUNDICE IN THE NEWBORN: ALGORITHMIC DIAGNOSIS OF CONJUGATED AND UNCONJUGATED HYPERBILIRUBINEMIA. (Eng.) Thaler, M. M. (Dept. Pediatrics, Univ. California, San Francisco, CA 94122). *JAMA* 237(1):58-62; 1977.

The use of algorithms in the differential diagnosis of jaundice in newborns and young infants is discussed on the basis of studies on bilirubin metabolism, causes of unconjugated neonatal bilirubinemia, and conditions associated with conjugated hyperbilirubinemia. The fraction diazo reaction on serum was used to measure the total bilirubin level and the conjugated fraction in the jaundiced infant; hyperbilirubinemia can thus be classified as conjugated or unconjugated (<15% of total bilirubin conjugated). The presence of unconjugated hyperbilirubinemia at birth to 2 days of age may indicate erythroblastosis. The key determination is the direct Coombs test, which is used to detect blood type incompatibility. The majority of infants with unconjugated hyperbilirubinemia at 3-7 days of age have physiologic hyperbilirubinemia, which may be complicated by prematurity, hypoxic states, acidosis, or hypoglycemia. Several congenital hematological disorders (RBC enzymopathies, spherocytosis, aplastic or hypoplastic anemia), hypothyroidism, and perinatal complications (hemorrhage, sepsis) may be manifested by unconjugated hyperbilirubinemia at 1-8 weeks of age. In conjugated hyperbilirubinemia, the main diagnostic problem is to distinguish intrahepatic from extrahepatic causes. Standard liver function tests are not helpful for this purpose in early infancy, with the exception of the occurrence of rapidly rising serum alkaline phosphatase and cholesterol concentrations; this suggests involvement of intrahepatic terminal bile ducts in a destructive process, which leads to intrahepatic biliary hypoplasia or paucity of interlobular bile ducts. The presence of characteristic facies, congenital heart defects, and vertebral malformations help to identify intrahepatic biliary hypoplasia.

4278 APOA-I AND A-II CONCENTRATIONS IN PROLONGED OBSTRUCTIVE JAUNDICE (POJI) OF INFANCY [Abstract]. (Eng.) George, P. K.; Zvargulis, J. E.; Keating, J.; Schonfeld, G. (Dept. Preventive Medicine, Washington Univ., St. Louis, MO). *Clin. Res.* 25(3):311A; 1977.

Nonviral Hepatitis and Hepatic Injury

4279 ELECTRON MICROSCOPIC PICTURE OF OXYPHENISATIN-INDUCED LIVER LESION. (Ger.) Merker, H. J.; Henning, H.; Vogel, H. M. (Freie Universitat Berlin, Berlin, W. Germany). *Z. Gastroenterol.* 14(8):779-795; 1976.

Biopsy samples obtained during laparoscopy of 20 patients with oxyphenisatin-induced liver damage were studied by electron microscopy. The cells in the lesions showed nuclear changes (nucleolar segregation and chromatin condensation), fragmentation and "disarrangement" of the endoplasmic reticulum, and loss of ribosomes; mitochondrial swelling was observed only in some of the cells. Lipid inclusions and isolated inclusions were interpreted as lysosomal restiform bodies. The attack point of oxyphenisatin (phenolisatin) preparations may be the cell nucleus or nucleolus. Pathological changes described by light microscopy studies are corroborated by electron microscopy.

4280 INHIBITION OF GALACTOSAMINE HEPATITIS IN THE RAT BY α_M-FETOPROTEIN: AN ACUTE PHASE REACTANT [Abstract]. (Eng.) van Gool, J.; de Nie, I.; Boers, W. (Lab. Experimental Medicine, Wilhelmina Gasthuis, Univ. Amsterdam, Netherlands). *Digestion* 14(5/6):516-517; 1976.

4281 ISONIAZID FULMINANT HEPATITIS IN PATIENTS RECEIVING RIFAMPICIN: A POSSIBLE CONSEQUENCE OF ENZYME INDUCTION [Abstract]. (Eng.) Pessayre, D.; Bentata, M.; Degott, C.; Nouel, O.; Miguet, J. P.; Rueff, B.; *et al.* (Hopital Beaujon, Clichy, France). *Digestion* 14(5/6):535; 1976.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

4282 RISK OF HEPATITIS TRANSMISSION BY GASTROSCOPY? (Ita.) Massarat, S.; Urban, M.; Schiff, W. (Medizinische Universitats-Poliklinik, Robert-Koch-Str. 7a, 355 Marburg, W. Germany). *Minerva Med.* 66(63):3257-3260; 1975.

The risk of hepatitis contamination by gastroscope was evaluated in 211 patients with various gastroenteric diseases. Five of the patients (three with chronic hepatitis, one with achlorhydria, and one with duodenal ulcer) were hepatitis B antigen-positive before gastroscopy, while one patient with cirrhosis of the liver was hepatitis B antibody positive. All patients were subjected to gastroscopy performed with the same gastroscope (Olympus GIF type D), which, before each gastroscopy, was first washed with water, then immersed for 20-30 min in a commercial disinfecting solution, and finally passed through 70% alcohol. The evaluation was made about 2 months (59 ± 8 days) after gastroscopy in 200 patients (8 died before the examination; 3 did not return for checkup), and also about 4 months (124 ± 14 days) after gastroscopy in the remaining 196 (4 other patients died between the first and second evaluation). Only 2/206 hepatitis B antigen-negative patients (1 with carcinoma of the stomach and 1 with liver cirrhosis) were found to be hepatitis B antigen positive after gastroscopy. However, the presence of the hepatitis B antigen was attributed to albumin infusions received after gastric surgery in the first patient, and to the pre-existing disease in the second. Another patient, with gastric ulcer, became hepatitis B antibody-positive. The possibility of hepatitis contamination by gastroscopy is very remote, and a routine determination of the hepatitis B antigen before gastroscopy does not appear to be required. It is not known whether the absence of contamination was due to insufficient quantities of virus or to the virucidal action of the disinfecting method.

4283 VERTICAL TRANSMISSION OF VIRAL HEPATITIS TYPE B. (Cze.) Vanista, J. (Infekcni klinika University Karlovy, 180 81 Prague 8-Bulovka, Czechoslovakia). *Cas. Lek. Cesk.* 116(7):193-196; 1977.

Twenty children (aged 2 weeks to >4 yr) of mothers with hepatitis B of pregnancy or in pueriperium were studied for the presence of the hepatitis B (HB) antigen in the serum using reverse immunoelectrophoresis. The antigen was found in six children. Internal clinical findings in these children were normal, but in four, there were biochemical signs of liver damage (anicteric pathology in 2, serum transaminase levels at the upper limit of normal in 2). The presence of HB in pregnant or puerperal women may thus result in vertical transmission of the infection from mother to child, particularly if the mother contracts the infection during the final months of pregnancy or during puerperium, and especially if the antigen is present in the mother's body at the time of childbirth. HB antigen was not detected in either umbilical blood of the mother's milk. Certain measures should be taken to ensure early detection of perinatal transmission of HB antigen in pregnant women with HB and to monitor the health of their children. Mothers with HB antigenemia should not nurse their children. No prophylactic effect of normal immunoglobulin was noted.

4284 INTRAUTERINE VIRAL HEPATITIS. (Rus.) Bulatkina, Z. G. (Leningrad Pediatric Medical Inst., Leningrad, USSR). *Vopr. Okhr. Materin. Det.* 21(10):20-22; 1976.

The effects of viral hepatitis were studied in 51 children (40 neonates and 11 stillborns) and in 127 pregnant women and their fetuses (128). During pregnancy, 78.4% of the mothers had various diseases: 24.9% had hepatitis and 18.3% had viral respiratory infections. Severe forms of congenital hepatitis were recorded in 70% of the patients: 68.6% of the children had chronic hepatitis with cirrhosis and 11 neonates died of hepatitis. All neonates had elevated bilirubin levels (5.7 ± 0.6 mg%); bilirubin content was maximum in cirrhotic patients (14.2 ± 1.2 mg%). In the 127 pregnant women, 54.3% had premature births or miscarriages (14.1% stillborns) and 1.6% of the children had congenital malformations. Subclinical manifestations of hepatitis were observed in 11 newborns. Of 18 stillborns, 3 had jaundice and 7 showed enlargement of the liver. Fifty children were followed up for 4-10 yr; dysgenesis (syndactylia, third eyelid, and hard palate) were frequently observed and 16% of these children were mentally retarded.

4285 HEPATITIS B VIRUS INFECTION IN DENTAL SURGICAL PRACTICE.

(Eng.) Goubran, G. F.; Cullens, H.; Zuckerman, A. J.; Feddleston, A. L. W.; Williams, R. (Queen Victoria Hosp., East Grinstead, Sussex, England). *Br. Med. J.* 2(6035): 559-560; 1976.

Sixty-one dental surgeons were interviewed to establish the incidence of attacks of viral hepatitis and to relate this to environmental risk factors. Six (10%) had a history of hepatitis, in one case due to infection with the hepatitis B virus. Screening blood of the 61 subjects for hepatitis B surface antigen (HBsAg) by radioimmunoassay showed no carriers of the antigen, but transient antigenemia was observed in one dentist. Antibody to HBsAg was detected in four dentists (7%), only one of whom had had clinical hepatitis. Dental surgeons may be more at risk from infection with the hepatitis B virus than the general population, although this risk should be minimized in hospital practice, where most infected patients will already have been identified and appropriate precautions can be taken. The risk of transmission from an antigen-positive dentist to his patients is probably much smaller than the risk to the dentist from his patients, and there is no evidence to indicate that he should restrict his clinical activities.

4286 OBSERVATIONS ON 2000 CHRONIC CARRIERS OF HBs ANTIGEN.

(Fre.) Courouce-Pauty, A. M.; Soulier, J. P. (Centre National de Transfusion Sanguine, 6, rue Alexandre-Cabenel, 75739 Paris, France). *Sem. Hop. Paris* 53(22/23):1327-1335; 1977.

The evaluation of 2,000 blood donors for the presence of hepatitis B antigen (HBsAg) was carried out since 1969, and the findings are related to donor age, sex, blood group, liver function tests, and where possible, to familial incidence. The incidence of HBsAg was four times greater among French donors than non-French donors, and three times greater among men than women. Donors younger than 35 yr were twice as likely to be HBsAg+, and the incidence increases again after 54 yr. The major sub-types *ad/ay* ratio in French donors is 2.6 and does not vary with age. In group O donors it is 1.6. Of the HBsAg donors, 78.5% had normal liver function tests (women, 91.5%; men, 73.4%); high HBs titers were observed in 45.6%. The incidence of eight HBsAg subtypes in 11 countries represented by the screened blood donors is presented. The most frequently appearing subtype was *adw* 2 (69.7% of the French and 72% of the Antilles sample). Intrafamilial incidence was noted in 39/2,000 donors (19 families). The findings of the present study are compared with those reported in the literature. The higher frequency of HBsAg in Mediterranean and tropical countries; the absence of correlation between the ABO system and HBsAg; the correlation between sex, age, and HBsAg incidence; and the proportion of subtypes as a function of age and country of origin are in agreement with previously reported data.

4287 PROGNOSIS OF VIRAL HEPATITIS IN CHILDREN: REPORT OF 470 PATIENTS BEING CARED FOR AT HOME.

(Fre.) Toppet, M.; Rodesch, P.; Cadranel, S. (Avenue Gabriel Faure 4, B-1190 Brussels, Belgium). *Acta Gastroenterol. Belg.* 39(9/10):334-339; 1976.

The prognosis of 470 cases of childhood viral hepatitis (VH) over a 5-yr period is reported. Hepatitis B surface antigen (HBsAg) was determined in 391 children, mainly by complement fixation and/or immunoelectrophoresis. The frequency of type A VH was very high at 5 yr of age and it usually peaked in January and September. This was not evident in type B VH. Children were considered cured if the results of clinical tests and hepatic function (essentially the transaminases) became normal. Type A VH is usually cured within 4 weeks, but type B VH is more persistent. Of 65 children with type B, 13 had a chronic course lasting longer than 6 months, compared with 6/274 patients with type A. A liver biopsy by laparoscopy in 34 children with an unfavorable course in two. The results demonstrated that type B VH is more aggressive than type A in children and that clinical recovery should not be assumed unless confirmed by biological data. A histological examination should be performed after the first 4 months of evolution of VH, especially if the HBsAg persists in the blood.

4288 INTRAHEPATOCYTIC LOCALIZATION OF HBs AND HBc ANTIGENS: AN IMMUNOFLUORESCENCE AND IMMUNO-ULTRASTRUCTURAL STUDY.

(Fre.) Thery, J. P.; Stoebner, P.; Bonnet-Eymard, J. (C.H.U. de Grenoble, Les Sablons, 38700 La Tronche, France). *Gastroenterol. Clin. Biol.* 1(2):117-126; 1977.

The results of indirect immunofluorescence, conventional electron microscopy, and indirect immunoelectron microscopy (with peroxidase) used to determine the localization of surface (HBs) and core (HBc) hepatitis B antigens (Ag) in hepatocytes are presented. The study was done on seven HBs+ patients and one control patient with gastric carcinoma. Serum HBsAg levels were determined by electroimmunodiffusion and passive hemagglutination. In the presence of anti-HBs antibodies, peroxidase invariably stained the cytoplasm but never the nucleus. In these peroxidase-stained cells, HBsAg was localized in smooth endoplasmic reticulum and in the tubular formations they contained. The hepatocyte nuclei of serum HBsAg+ patients contained spherical particles (average diameter=19 nm) in a generally circular formation, several of which contained a central osmophilic punctation. Following incubation with anti-HBc antibodies, dense, homogeneous nuclear fluorescence was noted; the cytoplasm was clear. The same effect was noted with anti-HBc antibodies in the presence of peroxidase.

4289 IDENTIFICATION OF HBs ANTIGEN BY INDIRECT IMMUNOFLUORESCENCE ON PARAFFIN SECTIONS OF THE LIVER IN PATIENTS WITH DIFFERENT TYPES OF VIRAL HEPATITIS.

(Fre.) Molas, C.; Voillemot, N.; Potet, F. (Hopital Beaujon, Clichy, France). *Gastroenterol. Clin. Biol.* 1(3):249-256; 1977.

An evaluation of hepatitis B specific antigen (HBsAg) in 53 liver biopsies from 50 patients (30 HBsAg+; 20 HBsAg-) is presented. Chief pathology among the controls were: HBsAg-negative hepatitis (5/20), chronic alcoholism (8/20), hematologic disorders (3/20), infections (2/20), tumoral (1/20), and cardiac (1/20). On the basis of clinical, biological (sedimentation rate, gammaglobulins, and transaminases), histological, and evolutive evidence, serum HBs+ patients were classed in five groups: healthy carrier (11), acute hepatitis (4), persistent chronic hepatitis (6), active chronic hepatitis (2), and cirrhosis (7). Several sections of biopsies from each patient were fixed separately in Bouin's and paraformaldehyde solutions. Immunofluorescence examination was carried out by standard technique on deparaffinized sections incubated first in anti-HBs sheep serum and then in fluoresceine-labeled rabbit anti-sheep serum, and the number of positive cells noted (1-5%=+1; 10-40%=+2; 50%=+3). Results from both Bouin's and paraformaldehyde fixed material were the same, but background fluorescence was more significant in the Bouin's prepared sections. When HBsAg is present it is invariably cytoplasmic, never nuclear. HBsAg was noted in the cells of all patients with HBsAg + serum. Distribution and abundance of hepatocytic HBsAg differed markedly from patient to patient, and no correlation with type of liver pathology was noted. Only a few patients with HBsAg+ serum demonstrated "ground glass" hepatocytes. The latter were orcein as well as HBsAg+.

4290 DETECTION OF HBs AND HBc ANTIGENS IN HUMAN LIVER BIOPSIES BY IMMUNOFLUORESCENCE AND ORCEIN STAINING.

(Fre.) Buffet, C.; Briantias, M. J.; Chaput, J. C.; Rain, B.; Martin, E.; Etienne, J. P. (Hopital Antoine-Beclere, 157, rue de la Porte-de-Trivaux, 94241 Clarmont, France). *Gastroenterol. Clin. Biol.* 1(2):127-137; 1977.

Human hepatic hepatitis B surface (HBs) and hepatitis B core (HBc) antigens were evaluated by indirect immunofluorescence and orcein staining in 80 liver biopsies from 71 patients. Of these, 56/71 patients (65 biopsies) were serum HBs carriers, and were classed into four groups: acute viral hepatitis (19), chronic hepatopathy with and without cirrhosis (29), and asymptomatic chronic carriers (8). Fifteen biopsies from 15 patients lacking serum HBs tigen comprised the remainder of the study material. HBs-positive cells showed a cytoplasmic fluorescence; HBc-positive cells showed a nuclear fluorescence. Hepatocytes from serum HBs-negative patients showed neither cytoplasmic nor nuclear fluorescence. Of 19 biopsies from acute viral hepatitis patients, 1 was positive by indirect immunofluorescence. Of 20 biopsies from patients with chronic hepatitis without cirrhosis, 10 were positive; 8/18 biopsies from patients with chronic hepatitis with cirrhosis were positive. All eight biopsies from eight chronic asymptomatic carriers were positive. The results indicate that: 1) the number of positive hepatocytes in relation to the total number of hepatocytes is low in the majority of cases; 2) there appears to be no difference between types of liver pathology and the number of positive hepatocytes; 3) distribution of positive hepatocytes is diffuse in chronic hepatitis without cirrhosis, and focal in chronic hepatitis with cirrhosis; and 4) there is no correlation between serum HBs-positive levels and the number of positive hepatocytes in corresponding biopsy material. It was also noted that HBc fluorescence was never positive in patients with acute viral hepatitis.

4291 ORCEIN POSITIVE HEPATOCELLULAR MATERIAL IN LONG-STANDING BILIARY DISEASES. I. HISTOCHEMICAL CHARACTERISTICS.

(Eng.) Sipponen, P. (Central Lab. Pathology, Univ. Helsinki, Helsinki, Finland). *Scand. J. Gastroenterol.* 11:545-552; 1976.

Histochemical studies were made to determine the composition of an orcein-positive material observed to accumulate in liver cells during long term biliary diseases. Liver biopsies from five patients with primary biliary cirrhosis were studied. The material became orcein-positive after previous oxidation. Staining reactions of the material with orcein at pH 2.0 and aldehyde fuchsin or alcian blue at pH 0.2 under various conditions indicated the presence of sulfonic acid residues and that the material is protein in nature. Positive Rubeanic acid and Mallory-Parker's hematoxylin tests in the area of orcein-positive material indicated that the protein is complexed with copper. The staining characteristics of the orcein-positive material were different from those caused by bile pigments as well as various orcein-positive factors that may occur in liver diseases, such as lipofuschins and viruses. The possibility is raised that the accumulation of copper-protein complexes in liver cells indicates insufficient excretion of bile and a progression of biliary disease to cirrhosis.

4292 INHIBITORY ACTIVITY IN SERA FROM PATIENTS WITH ACUTE AND CHRONIC HEPATITIS AND ITS CLINICAL SIGNIFICANCE.

(Eng.) Brattig, N.; Berg, P. A. (Medizinische Universitatsklinik, D-74 Tubingen, W. Germany). *Minerva Gastroenterol.* 22(3):191-198; 1976.

The inhibitory serum factors that block phytohemagglutinin (PHA)-induced transformation of lymphocytes in sera from patients with acute and chronic liver diseases were studied to learn the clinical significance of these blocking factors. The use of this inhibition reaction as a prognostic marker in various forms of chronic liver disease was also investigated. Thirteen patients with acute hepatitis B surface antigen (HBsAg)-positive viral hepatitis were tested for PHA-induced lymphocyte transformation, and sera from nine patients with viral hepatitis were tested for inhibitory activity. Inhibition was also measured in 35 patients with chronic hepatitis, 10 with primary biliary cirrhosis, 14 with pseudolupus erythematosus, 24 with collagen disease, and 15 with myocardial infarct. In the sera from the nine patients with acute viral hepatitis, inhibitory activity was observed only transiently at the early stage of the disease. Sera from patients with chronic hepatitis showed only a weak inhibition. Inhibitory activity was also observed in sera from patients with various other diseases, especially patients with lupus erythematosus, rheumatoid arthritis, and drug-induced pseudolupus erythematosus. Sera from patients with myocardial infarct did not inhibit lymphocyte transformation. Inhibitory activity was not influenced by factors like HBsAg, increased bilirubin levels, or other biochemical factors. Since lymphotoxic antibodies are found in many viral diseases one could postulate that T-cell antibodies may arise as a result of cross-reaction between viral and lymphocyte surface antigens. Blocking of T-lymphocyte activity may be caused by antigen-antibody complexes in a specific and nonspecific way: specifically, by the binding via the antigen and unspecifically, via the Fc receptor.

4293 ALPHA-1-FETOPROTEIN IN ACUTE HEPATITIS.

(Ita.) Furfaro, M.; Pesce, G. (Ente Ospedaliero San Paolo, Savona, Italy). *Pathologica* 67(965/966):125-129; 1975.

The possible presence of α-1-fetoprotein (AFP) was studied in samples of blood serum from 692 patients with acute liver disease of presumable viral origin (506 with infectious hepatitis; 86 with serum hepatitis); sera from the umbilical cord blood of 100 normal newborn babies, and from 100 healthy adults were also tested. The investigation was made with the "Mancini's Technique," using commercial Hoechst-Behringwerke "immunoplates;" this immunochemical method has an optimum detection limit of 1 mg/100 ml and is much less sensitive than radioimmunoassays (RIA). The results showed no AFP presence in the 692 patients with hepatitis and the 100 healthy adults. AFP was readily detectable in the blood serum of all 100 newborn. The results corroborate previous reports that icterogenic acute hepatitis, with long or short incubation and with or without presence of hepatitis B antigen or its corresponding HB antibody, does not induce an active hepatic regeneration process and consequent appearance of high AFP levels. Only exceptional cases of liver diseases and some neoplasms (hepatoma; teratoblastoma) may induce recuperation of the AFP synthesis with appearance of high AFP levels detectable by immunochemical methods. Immunochemical methods are useful in the diagnosis of primary hepatic carcinoma and testicular teratoblastoma, while very small amounts of AFP can only be detected by RIA methods.

4294 NOTES ON THE EFFECT OF A PHOSPHORYLATED GLYCO-DERIVATIVE IN 30 CASES OF ACUTE VIRAL HEPATITIS.

(Ita.) Fiori, G. P.; Mazza, L. (Divisione Malattie Infettive e Laboratorio di Patologia Clinica, Ospedale Civile, Alessandria, Italy). *Minerva Med.* 67(12):732-740; 1975.

The effects of treatment with uridine diphosphate glucose (UDPG) on clinical symptoms and laboratory parameters indicative of hepatic function impairment were studied in 30 patients with acute viral hepatitis. The UDPG was administered in 500 cm^3 of 15% levulose solution in two different doses: 50 mg/day x 16-34, i.v., in 15 patients and 20 mg/day x 19-55, i.v., in the other 15 patients. All patients received supplementary treatment with a preparation of liver extract plus vitamin B_{12} and a polyvitamin preparation plus a hepatoprotective substance. Clinical evaluations made on the 7th and 15th days of treatment showed a definite diminution of the asthenia, dyspeptic and intestinal disturbances, hepatomegaly, splenomegaly, and urinary pigmentation; a linear decrease was noted in the levels of total and direct reaction bilirubin, SGOT, SGPT, alkaline phosphatase, serum Fe, proteinemia, hemoglobin (Hb), and glycemia. Linear increase of the albumin-to-globulin ratio, hypothrombinemia, and fecal pigmentation was also noted. The rate of effectiveness was similar with both doses, except for proteinemia in which the linearity was valid only with the 20-mg dose, and for Hb and glycemia in which it was valid for the 50-mg dose only. The overall results, however, indicated the superiority of the 50-mg dose. Most of the parameters studied showed a tendency towards normalization at the end of the treatment; there were no side-effects. The statistical evaluation of the results confirmed the validity of the clinical observations. The authors imply that UDPG is definitely active and therapeutically effective in the treatment of acute severe liver diseases.

4295 VARIATIONS IN PLASMA AMINO ACIDS DURING SEVERE HEPATITIS WITH ENCEPHALOPATHY.

(Fre.) Delafosse, B.; Bouletreau, P.; Motin, J. (Hopital Edouard Herriot, place d'Arsonval, F 69374 Lyon Cedex 2, France). *Nouv. Presse Med.* 6(14):1207-1211; 1977.

Plasma amino acid (PAA) levels were monitored 36 times in 10 patients in the course of severe viral hepatitis with encephalopathy (9) or toxic hepatitis from *Ammanita phalloides* mushroom (1) and in 12 healthy controls. At the time of hospitalization, prothrombin levels were less than 20%, and the SGOT levels varied from 1,900-5,000 U; blood ammonia ranged from 130 to 200 μg/100 ml. Glucose was given i.v. and stage II and III comatous patients were also given artificial respiration. Only 4/10 patients survived, and 6/10 died within 24 hr to 11 days after admission. Plasma levels of the aromatic amines, phenylalanine, tyrosine, and methionine were identical in controls and subjects with hepatocellular failure without encephalopathy (3 patients), while they were significantly elevated in hepatic encephalopathy (7 patients). No variations in aliphatic acid amines (valine, leucine, and isoleucine) were noted in controls, and they were below normal in patients with or without encephalopathy. A significant decrease was noted only in valine levels in patients with hepatocellular disease without encephalopathy. Other PAA levels were only elevated in cases of hepatic encephalopathy. The molar ratio of aliphatic amino acids to aromatic amino acids decreased significantly in conscious patients with severe hepatocellular failure and dropped significantly in patients with hepatic encephalopathy. No relation between PAA levels and the degree of encephalopathy was noted.

4296 CONTRASTING FEATURES AND RESPONSES TO TREATMENT OF SEVERE CHRONIC ACTIVE LIVER DISEASE WITH AND WITHOUT HEPATITIS Bs ANTIGEN. (Eng.) Schalm, S. W.; Summerskill, W. H. J.; Gitnick, G. L.; Elveback, L. R. (Mayo Clinic and Mayo Foundation, Rochester, MN). *Gut* 17(10):781-786; 1976.

A comparison of hepatitis B surface antigen (HBsAg)-positive and negative patients with severe chronic active liver disease (CALD) was made to investigate differences in response to therapy as well as to clarify variations in initial clinical and immunoserological features. HBsAg-positive patients were predominantly males (89%) over the age of 40 yr (median age, 52 yr) and more frequently failed to respond to conventional treatment programs with prednisone. In contrast, HBsAg-negative patients were more often female (70%) and younger (median age, 35 yr), had a higher incidence of associated immunopathic disease and immunoserological markers in high titer, and more often responded to treatment with full remission of their disease. The percentages of clinical and biochemical resolutions, histological remissions, treatment failures, and deaths among 82 HBsAg-negative patients were 80, 68, 16, and 11%, resp., as compared to corresponding percentages of 46, 15, 46, and 31%, resp., for 13 HBsAg-positive patients. The 2-yr survival for the 82 HBsAg-negative patients over 90% as compared with less than 70% for the 13 HBsAg-positive patients and about 50% for 29 control patients (26 HBsAg-negative and 3 HBsAg-positive patients). Initial responses of HBsAg-positive patients to 69-mg/day doses of prednisone or to prednisone (30 mg/day) in combination with azathioprine (50 mg/day) were usually as favorable as in HBsAg-negative patients. However, when the doses were reduced to conventional maintenance levels (20 mg/day), biochemical deterioration followed in 6 of 11 surviving HBsAg-positive patients and in only 1 of 13 HBsAg-negative patients. Reinstitution of higher prednisone doses resulted in biochemical improvement in all patients. Among 10 HBsAg-positive patients who were followed for more than 1 yr, antigen persisted in 8, 7 of whom have required continuing treatment. In two patients (under 40 yr of age) antigenemia was transient; one reached full remission and discontinued treatment 2 yr ago. The benefit/risk ratio of both conventional and high doses of prednisone in HBsAg-positive severe CALD requires further clarification.

4297 ABSENCE OF COMPLETE HOMOLOGOUS IMMUNITY IN HEPATITIS B INFECTION AFTER MASSIVE EXPOSURE. (Eng.) Trepo, C. G.; Prince, A. M. (New York Blood Center, New York, NY). *Ann. Intern. Med.* 85 (4):427-430; 1976.

The question of whether immunity to hepatitis B infection can be overcome by massive challenge doses was studied in three experimentally challenged chimpanzees. Observations were also made in 299 cardiac surgery patients after blood transfusions. Thirteen patients showed an anamnestic antibody response to hepatitis B surface antigen (anti-HBsAg); an eightfold or greater titer rise occurred within 4 weeks of transfusion. Three of these patients developed anicteric, asymptomatic hepatitis. The three chimpanzees developed hepatitis and hepatitis B surface antigenemia when challenged with hepatitis B virus that had an antigenic subtype identical to that used in the primary infection. This response provides evidence against the role of differences in antigenic composition of initial and challenge strains of virus as an explanation for incomplete homologous immunity. The results indicate that immunity to hepatitis B infection can be overcome by massive challenge doses.

4298 DEVELOPMENT OF IMMUNITY AGAINST HEPATITIS A VIRUS BY SUBCLINICAL INFECTION. (Eng.) Villarejos, V. M.; Gutierrez-Diermissen, A.; Anderson-Visona, K.; Rodriguez-Aragones, A.; Provost, P. J.; Hilleman, M. R. (Intl. Center for Medical Research and Training, San Jose, Costa Rica). *Proc. Soc. Exp. Biol. Med.* 153(2):205-208; 1976.

A new immune adherence test for hepatitis A antibody was applied to etiologic investigations of 25 cases of subclinical hepatitis diagnosed by serum enzyme elevations. Eighteen cases seroconverted and were diagnosed as hepatitis A, four were hepatitis B surface antigen, and three cases were neither A nor B. The 18 patients with hepatitis A antibody were followed up for 2-7 yr, and the antibody titers remained unchanged during this period. The development of hepatitis A antibody equates with protection against the disease and confirms the suggestion that immunity may result from clinically inapparent infection.

4299 IMMUNE MECHANISMS IN HEPATITIS B: NEW ASPECTS AND PRACTICAL CONSEQUENCES. (Fre.) Frei, P. C. (Departement de medecine, CHUV, CH-1011, Lausanne, Switzerland). *Schweiz. Med. Wochenschr.* 107(15):510-514; 1977.

A review of the different types of immune responses occurring during hepatitis B infections shows that the specific responses for hepatitis B surface antigen (HBsAg) are important in the pathogenesis of chronic liver disease. Anti-HBsAg antibodies are only detected in the serum several weeks after infection commences. These antibodies are not cytolytic by themselves nor do they exert a protective effect when the virus is already intracellular. Antibodies to HBsAg have been demonstrated on circulating lymphocytes. When purified, HBsAg is capable of the *in vitro* induction of blastogenesis in individual lymphocytes of patients who have recovered from acute hepatitis. The leukocyte migration inhibition test performed before and after acute hepatitis B and in asymptomatic carriers indicates that the hepatic lesion is probably due to cell-mediated immunity for HBsAg, which causes cytolysis of the hepatocytes. Immune complexes were detected in 14/19 patients with chronic active hepatitis, 13/17 patients with posthepatic cirrhosis, and in 13/18 patients with acute hepatitis. They were also present in 10/18 patients with persistent hepatitis, 7/15 asymptomatic carriers, and in 1/10 patients cured of acute hepatitis. These complexes may play a pathogenic role in some forms of chronic active hepatic diseases.

LIVER AND BILIARY TRACT

Chronic Hepatitis

4307 CHARACTERISTICS OF THE COURSE OF CHRONIC HEPATITIS IN CHILDREN WITH HEPATITIS B ANTIGEN. (Rus.) Glozand, I. V.; Blagoslovensky, G. S.; Popova, L. A.; Bragin, V. P. (Leningrad Scientific Res. Inst. of Children's Infections, Leningrad, USSR). *Pediatriia* 7:21-24; 1976.

The incidence of hepatitis B antigenemia was studied in 226 children with chronic hepatitis. A previous history of acute disease was recorded in 85.6% of the children (61.2% had an anicteric variant and 24.4% had an icteric variant). Chronic hepatitis occurred more frequently in children aged 3-7 yr. Hepatitis B antigen was observed in 51.8 ± 3.5% of the patients; the frequency of antigenemia was higher in the patients with active disease (63.6 ± 10.5%), than in the patients in remission (43.8 ± 3.8%). Remission was observed in 37.0 ± 5.2% of the patients with persistent antigen and in 59.0 ± 5.5% of those without persistent antigen. Persistent antigen was detected in 30% of the children with concomitant chronic diseases (28% entered the remission) and in 16% of the children without concomitant chronic diseases (58% were in remission).

4308 CONTROLLED TRIAL OF SYNTHETIC D-PENICILLAMINE AND PREDNISONE IN MAINTENANCE THERAPY FOR ACTIVE CHRONIC HEPATITIS. (Eng.) Stern, R. B.; Wilkinson, S. P.; Howorth, P. J. N.; Williams, R. (Middlesex Hosp., Mortimer St., London WC1, England). *Gut* 18(1):19-22; 1977.

The use of D-penicillamine in the treatment of active chronic hepatitis was evaluated in 35 patients, and its usefulness was compared with that of prednisone. Eighteen patients received D-penicillamine (increasing from 600 mg to 1.2 g/day), and 17 received prednisone (15 mg/day). In all patients, hepatitis had already been brought under biochemical control with corticosteroids. During the first yr of the trial, the treatment of nine patients in the D-penicillamine group was discontinued (2 because of lack of disease control and 7 because of side-effects) compared with six patients in the prednisone group (4 because of lack of disease control, 1 because of side-effects, and 1 because of the development of carcinomatosis). Detailed statistical analysis of the liver function tests in the patients remaining in the trial at the end of the year showed no significant differences. D-penicillamine is associated with a higher frequency of side-effects than is prednisone, and cannot be considered the treatment of choice in maintenance therapy for active chronic hepatitis. However, in some patients it is as satisfactory as prednisone in controlling the disease.

4309 LIVER CELL SURFACE LOCALIZATION OF HEPATITIS B ANTIGEN AND OF IMMUNOGLOBULINS IN ACUTE AND CHRONIC HEPATITIS AND IN LIVER CIRRHOSIS. (Eng.) Alberti, A.; Realdi, G.; Tremolada, F.; Spina, G. P. (Istituto di Medicina Clinica, Univ. Padua, Padua, Italy). *Clin. Exp. Immunol.* 25(3):396-402; 1976.

Results of immunofluorescence studies on liver cell-surface localization of hepatitis B surface antigen (HBsAg) and of IgG in acute hepatitis (18 patients) and chronic hepatitis or cirrhosis (27 patients) are reported. In acute hepatitis B, HBsAg was found at the surface of hepatocytes in the early phase of the disease (6 of 9 patients studied), but not during recovery. The number of positive cells ranged from 6 to 27%. A surface localization of IgG was found in two cases, both positive for HBsAg. In HBsAg-positive chronic hepatitis (10 patients) and cirrhosis, the antigen was found in the cytoplasm of hepatocytes, but not on the surface of the hepatocytes, while in HBsAg-negative cases (17 patients), the antigen could not be detected in the liver cells. IgG was detected at the surface of liver cells in seven of nine patients with chronic active hepatitis, in three of seven with cryptogenic cirrhosis, and in none with chronic persistent hepatitis or alcoholic cirrhosis. Of the 10 patients with IgG bound to the hepatocyte surface, 5 showed HBsAg in the serum as well as in the cytoplasm of the hepatocytes. A role of antibodies in the pathogenesis of the disease is suggested.

4310 THE SIGNIFICANCE OF HBAg AND THE IMMUNE REACTION IN CHRONIC HEPATITIS. (Fre.) Nicolaescu, T.; Bittman, E.; Bordeianu, A.; Boros, I.; Gheorghe, N.; Stoiculescu, P. (Institut de Physiologie, 11, bd 1 Mai, Bucharest, Rumania). *Sem. Hop. Paris* 53(4):235-240; 1977.

The significance of hepatitis B antigen (HBAg) and immune reactions in chronic hepatitis was studied in 496 patients with chronic persistent (206) or aggressive hepatitis (CAH: 93) or with inactive (IHC: 108) or active (AHC: 89) hepatic cirrhosis, and in 390 patients with other digestive diseases. Also included were 64 blood donors in whom HBAg was detected by immunodiffusion or counter immunoelectrophoresis. HBAg was detected in the patients by immunofluorescence after liver biopsy. Of the 496 patients, the antigen was detected in 34.2%, mostly in the CAH patients (53.7% compared to 23.2% of the IHC patients). It was found that 43/64 apparently healthy blood donors had had previous chronic liver diseases. A randomized study of 50 patients with CAH and 50 with AHC revealed that 63 were positive for HBAg and 37 were negative. Hepatic tests in both of these groups were essentially similar; however, histochemically, patients with positive tests had a much greater frequency of intense mesenchymal activity and hepatocytic necrotic dystrophy. Patients with serum HBAg also had HBAg in the nuclei of the liver parenchyma cells. The rise in immunoglobulin G levels was also greater in these patients. There were no differences in the two groups with respect to antinuclear, anticytoplasmic, or smooth muscle antibody levels or the results of immune reactivity tests.

4311 HISTOCOMPATIBILITY ANTIGENS IN CHRONIC LIVER DISEASE. (Eng.) Scott, B. B.; Rajah, S. M.; Losowsky, M. S. (St. James' Hosp., Leeds LS9 7TF, Yorkshire, England). *Gastroenterology* 72(1):122-125; 1977.

The frequencies of histocompatibility antigens (HL-A) were determined in 25 patients with chronic active hepatitis, 15 with cryptogenic cirrhosis, and 18 with alcoholic cirrhosis and compared with those in 900 healthy controls. The frequencies of HL-A1, 2, 3, 9, 10, 11, 28, 29, 1 + 8, 5, 7, 12, 13, 14, 17, and 27, and of W5, W10, W15, W18, and W22 did not differ significantly in patients and controls. HL-A8 was significantly increased among the patients with cryptogenic cirrhosis as compared with controls (53% versus 27%, $p<0.05$), although the difference became insignificant if corrected for the total number of antigens tested; the frequency of this antigen among the other two patient groups and controls was not significantly different. The fact that the frequency of HL-A8 was not higher in patients with chronic active hepatitis, a phenomenon that has been reported in previous studies, could not be explained by differences in liver histology, serum biochemistry, or serum immunology.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

4318 MORPHOLOGY AND MORPHOGENESIS OF ALCOHOLIC LIVER CIRRHOSIS. (Rus.) Serov, V. V.; Labedev, S. P.; Mukhin, A. S. (First Moscow Medical Inst., Moscow, USSR). *Arkh. Patol.* 38(2):65-73; 1976.

The morphology and pathogenesis of alcoholic cirrhosis was observed in 42 liver biopsies from 32 patients of various ages. At least one biopsy was taken at laparoscopy from each patient, and repeat biopsies were realized by blind biospy. Cirrhosis was portal type in 26 patients, postnecrotic in 3, and mixed in 3. It is concluded that alcoholic cirrhosis is associated with multiple attacks of acute alcoholic hepatitis. After several episodes of alcoholic hepatitis, cirrhosis may change its morphological type from portal to postnecrotic or mixed type. In one patient, the first biopsy was diagnosed as portal cirrhosis; a biopsy repeat 2 yr later confirmed postnecrotic cirrhosis. Abstention from alcohol consumption resulted in stabilization of the histology and in disappearance of manifestations of exacerbation of cirrhosis. The study clarified the role of ethyl alcohol in progressive cirrhosis since every attack of acute alcoholic hepatitis was followed by postnecrotic-type liver pathology.

4319 DYNAMICS OF MORPHOLOGICAL CHANGES IN THE LIVER IN CHRONIC ALCOHOLISM. (Rus.) Serov, V. V.; Lebedev, S. P.; Mukhin, A. S. (First Moscow Medical Inst., Moscow, USSR). *Ter. Arkh.* 48(9):42-48; 1976.

Progressive stages of alcoholic lesion of the liver were studied in 140 patients with chronic alcoholism undergoing repeated liver biopsies. The majority of the patients were subjected to 2-4 biopsies at 0.5- to 4-yr intervals. Alcoholic degeneration of the liver was observed in 76 biopsy specimens. Repeated biopsies performed in the patients who abstained from alcohol showed that fatty degeneration was reversible. Alcoholic hepatitis was detected in 60 biopsies; 17 of 41 biopsies with features of acute alcoholic hepatitis also showed liver degeneration. Transformation of acute alcoholic hepatitis into chronic hepatitis was observed in 19 biopsies; three patients with acute alcoholic hepatitis developed chronic persistent hepatitis. Recurrences of the acute alcoholic hepatitis in the patients who developed persistent hepatitis were found to cause cirrhosis (2 patients). Alcoholic cirrhosis was found in 45 biopsies: 34 patients had alcoholic portal cirrhosis, 7 had postnecrotic cirrhosis, and 4 had mixed cirrhosis. Recurrences of acute alcoholic hepatitis (13 patients) could transform portal cirrhosis into mixed and postnecrotic hepatitis (2 patients). Chronic aggressive hepatitis was detected in four patients.

4320 THE BIOCHEMISTRY AND PATHOLOGY OF ALCOHOLIC LIVER DAMAGE. (Ger.) Eisenburg, J. (Klinikum Grosshadern, Medizinische Klinik II der Universitat Munchen, W. Germany). *Naturwissenschaften* 63(12): 556-569; 1976.

The problem of alcohol (AL) abuse associated with liver cirrhosis, which is among the leading causes of morbidity and mortality in the population between the ages of 25-65 yr in the Western countries, is reviewed with particular emphasis on the biochemical mechanism of liver damage. According to light microscopy, three characteristic AL-induced diseases are distinguishable: fatty liver, toxic liver, and cirrhosis. The latter two forms usually occur after years of AL consumption. Early liver changes are characterized by an increase in the size of hepatocytes and hypertrophy of the smooth endoplasmic reticulum. Further AL-induced changes are found in the Golgi apparatus in which activity of galactosyltransferase is sharply increased. Changes in the mitochondria include increase in size, subdivision of the outer membrane with increased permeability, change in density, deformation of the cristae, and paracrystalline inclusions. The accumulation of fat, an early and characteristic morphological liver change induced by AL, is caused by inhibition of fatty metabolism. Macroscopically, the liver is enlarged in the early stages of cirrhosis, but it decreases during the later stages and assumes a hard consistency with a nodulated superficial appearance. Evidently, the *de novo* synthesis of fibrinogen also plays a major role during this stage of the disease. The later stages of alcoholism may be accompanied by hepatoma.

4321 INCREASE OF SERUM MONOMERIC AND DIMERIC IMMUNOGLOBULIN A LEVELS IN ALCOHOLIC CIRRHOSIS. (Fre.) Andre, F.; Andre, C. (Unite de Recherches de Physiopathologie digestif, INSERM U-45, Hopital Edouard-Herriot, Pavillon H, F 69374 Lyon Cedex 2, France). *Biol. Gastroenterol. (Paris)* 9(2):147-150; 1976.

Monomeric and dimeric immunoglobulin A (IgA) concentrations were measured in 22 patients with alcoholic cirrhosis and 12 healthy volunteers (controls) by discontinuous sucrose gradient centrifugation and reduction alkylation. The patients had a statistically significant elevation in dimeric and monomeric IgA serum levels (7.28 and 2.41 times greater, resp.) compared with controls. A statistically significant elevation of IgM and IgG levels (by 1.84 and 1.56 times, resp.) was also detected in the patients. Double immunodiffusion showed that patient serum contained six times more IgA bound to the secretory component than control serum. Hypergammaglobulinemia A of alcoholic cirrhosis probably originates in the mucosa, since the increase in serum dimeric IgA is so much higher than that of the other immunoglobulins. Consequently, changes in the intestinal epithelium in cirrhosis undoubtedly are responsible for a deficit in the intestinal barrier, leading to the absorption of different antigens and inducing an immunological response.

4322 A STUDY ON MALLORY BODIES: ISOLATION, ULTRASTRUCTURE AND PRELIMINARY BIOCHEMICAL CHARACTERIZATION OF MALLORY BODIES FROM LIVERS OF ALCOHOLIC CIRRHOSIS AND MALIGNANT HEPATOMA. (Eng.) Okamura, K. (Tenri Hosp., Tenri, Nara 632, Japan). *Acta Pathol. Jpn.* 26(6):649-670; 1976.

Mallory bodies (MBs) were isolated from the livers of eight alcoholic patients and from a malignant hepatoma from a nonalcoholic patient using an improved centrifugal method (60% sucrose, 20,000 x *g* for 30 min) to investigate their mechanism of production. MBs were isolated in large quantity (100 mg-1 g wet pellet/1,000 g liver) and high purity (50 to 95%). The isolates were devoid of liver cell organelles except in the case of the malignant hepatoma where dense and membranous materia resembling nuclear substances and endoplasmic reticulum was found. The nuclear material had continuity with MBs. Electron microscopy suggested the presence of a dense body and very fine filaments within both *in situ* and isolated MBs in addition to the tubular structure of MB fibers The proportion of nonpolar amino acids in MB was small as compared with known fibrous proteins. MB protein solubilized in 6 M guanidine hydrochloride or 1% sodium dodecyl sulfate (SDS) with 2-mercaptoethanol and 8 M urea produced three peaks by Sephadex G-100 chromatography and at least five bands by SDS polyacrylamide gel electrophoresis. When examined spectrophotometrically, MB protein gave no absorption peak in the visual light range suggesting the absence of iron or copper. The results suggest that MBs are not newly synthesized protein but that protein components of MBs are similar to serum proteins and they are present in normal liver cells. It is suggested that MBs originate from nuclear material and serum proteins that are produced in the endoplasmic reticulum.

4323 LIVER FUNCTION IN CHRONIC ALCOHOLISM AND ITS CHANGES IN PROLONGED ABSTINENCE FROM ALCOHOL. (Rus.) Putalova, T. V. (Omsk Medical Inst., Omsk, USSR). *Klin. Med.* 54(10):81-85; 1976.

Chronic alcoholic men (105, aged 26-50 yr) were surveyed and divided into two groups: group 1 included 32 patients with stages I-II and II of alcoholism an group 2 included 73 men with stages II-III and III. Liver enlargement was observed in 33 patients; 16 patients complained of dyspepsia and pains in the right hypochondrium; and 13 complained of appetite loss, nausea, vomiting, and heartburn. The chronic alcoholic patients had significantly decreased albumin levels (44.04 ± 0.77% compared to 52.84 ± 1.38% in controls), elevated α_2-globulin levels (11.63 ± 0.25% compared to 8.71 ± 0.60% in controls) and β-globulins (14.61 ± 0.27% compared to 12.61 ± 0.59% i controls), reduced serum cholinesterase levels (128.0 ± 4.2% compared to 149.9 ± 5.3% in controls), and excessive BSP retention (6.57 ± 0.5% compared to 3.51 ± 0.01% in controls). Dysproteinemia was more pronounced in group 2 patients. Fifty-six patients underwent repeat examinations after 2 months of abstinence from alcohol, 36 after 6 months, and 35 after 1 yr. Dyspepsia and liver enlargement were found to undergo rapid regression, and at the end of the 1-yr follow-up, they were observed in only three patients. Nineteen patients showed complete normalization of liver function, 5 showed partial normalization, and functional disturbances of the liver were stable in 11 patients (all of them had 13- to 18 yr history of stage II-III chronic alcoholism).

4324 DUPUYTREN'S CONTRACTURE AND PALMAR ERYTHEMA IN ALCOHOLIC CIRRHOSIS. (Fre.) Bertrand, J.; Thomas, J.; Metman, E. H. (Chaire d'Hepatologie-Gastroenterologie, Faculte de Medecine, 2 bis, Blvd. Tonnelle, 37000 Tours, France). *Sem. Hop. Paris* 53(7):407-412; 1977.

The occurrence of Dupuytren's contracture and palmar erythema was compared in 100 patients with alcoholic cirrhosis (group I), 100 alcoholics without cirrhosis (group II), and 100 nonalcoholic, noncirrhotic controls (group III). Dupuytren's contracture was observed in 43% of group I, 34% of group II, and 14% of group III. Since there was no significant difference between groups I and II, the abnormality seemed more indicative of alcoholism than of liver disease. There appears to be a genetic component involved, but the clinical expression is facilitated by metabolic disorders, most frequently chronic alcoholism. Palmar erythema was present in 34% of group I, 23% of group II, and 12% of group III. It appears to be a manifestation of severe liver disease.

4325 ACUTE ALCOHOLIC HEPATITIS: DIAGNOSTIC CRITERIA, PROGNOSIS, AND TREATMENT. (Rus.) Mukhin, A. S.; Selindyeva, M. S.; Vinogradova, L. G.; Lebedev, S. P. (First Moscow Medical Inst., Moscow, USSR). *Ter. Arkh.* 48(9):30-42; 1976.

Of 150 patients with alcoholic lesions of the liver and 40 patients with chronic alcoholism followed up for 10 yr, 30 patients had acute alcoholic hepatitis (AAH). The average duration of alcoholism was 15 yr. Chief diagnostic manifestations of AAH were pain and dyspeptic syndromes, enlargement of the liver, elevation of the bilirubin level (up to 2 mg%), and increased activity of aminotransferases; two-thirds of the patients had nephropathy. Morphological examination of the liver specimens obtained at puncture biopsy showed necrosis of the hepatocytes, presence of Mallory bodies, and polynuclear infiltration of the portal stroma. Three clinical forms of AAH could be recognized: 10% of the patients had the latent form; the majority of patients had the icteric form; and 20% of the patients had the cholestatic form. Differential diagnosis between the latent form and fatty cirrhotic liver, and between the icteric and cholestatic forms and acute or viral hepatitis, could be arrived at only with liver biopsy.

4326 CLASSIFICATION OF ALCOHOLIC LIVER DISEASE: A MULTIDISCIPLINARY APPROACH [Abstract]. (Eng.) Hamlyn, A.; Lesna, M.; Watson, A. J. (Royal Victoria Infirmary, Newcastle upon Tyne, England). *Digestion* 14(5/6):517; 1976.

4327 IgA PATTERN IN LIVER TISSUE AS A DIAGNOSTIC TOOL IN ALCOHOLIC LIVER DISEASE [Abstract]. (Eng.) Kater, L.; Jobsis, A. C.; Vogten, A. J. M.; Grijm, R.; Baart de la Faille-Kuyper, E. H. (Univ. Hosp. Utrecht, Utrecht, Netherlands). *Digestion* 14(5/6):526; 1976.

4328 CHRONIC ALCOHOLISM AND LIVER CIRRHOSIS. (Rus.) Mansurov, Kh. Kh. (Inst. Gastroenterology, Tadzhik, SSR, USSR). *Klin. Med. (Mosk.)* 54(7):10-16; 1976.

LIVER AND BILIARY TRACT

Cirrhosis

4329 NEUROPATHY IN HEPATIC DISORDERS. (Eng.) Chari, V. R.; Katiyar, B. C.; Rastogi, B. L.; Bhattacharya, S. K. (Dept. Medicine, Banaras Hindu Univ., Varanasi, 221005, India). *J. Neurol. Sci.* 31(1):93-111; 1977.

Clinical, electrophysiological, and histological techniques were used to investigate the possibility of neuropathy in 30 patients with liver cirrhosis liver and in 12 patients with infective hepatitis. The results were compared to those obtained from 13 healthy individuals. Other possible conditions in which neural damage might occur such as old age, diabetes, and chronic alcoholism were excluded through screening. Clinical evidence of neuropathy was observed in 63.3% of the patients with cirrhosis of the liver, abnormal conduction velocities were found in 33.3%, and histopathological evidence of segmental demyelination and regeneration were observed in 80%. Only 16.6% of the patients with hepatitis showed clinvelocities were found in 41.6% and histopathological studies revealed segmental demyelination and regeneration in 75% of the patients. In patients with liver cirrhosis, neuropathy was found to affect the lower limbs most frequently. This study shows that neuropathy can occur in both chronic and acute hepatic disorders. Therefore, the cause may not be purely metabolic in origin, as previously thought.

4330 QUANTITATIVE HISTOLOGICAL ASPECTS OF LIVER CIRRHOSIS. (Eng.) Morselt, A. F.; Freni, S. C.; Ortlep, F. M. (Histological Lab., Jan Swammerdam Instituut, le Constantijn Huygensstraat 20, Amsterdam-Oud West, Netherlands). *Beitr. Pathol.* 159(2):195-206; 1976.

Data obtained with Feulgen DNA-cytophotometry of individual parenchymal cell nuclei of cirrhotic livers are described in combination with a topographic study of the distribution of polyploid nuclei. A large number of nuclei with very thin, peripheral, and finely meshed chromatin and large nucleoli were seen in cirrhotic livers, but no mitosis was seen. Nuclei considered to be in the S phase were more frequent in cirrhotic human livers (5 patients) than in livers from normal individuals (5 patients). Large quantitative differences in the percentages of diploid, tetraploid (up to 40%), and octoploid nuclei (20%) were found between different nodules of the cirrhotic livers. The lowest percentage of diploid nuclei occurring in normal liver (10 patients) was 80%, with 15-20% tetraploid nuclei. No more than four adjacent fields of view with increased degree of ploidy were found in normal livers, excluding livers containing much lipofuscin (10-20 adjacent fields). In the group with suspected liver disease and in the group with cirrhotic livers, up to 40 adjacent fields with an increased degree of ploidy could be found. The percentage of nodular mass varied from 10 to 100%, with an average of 30%. It is suggested that regeneration in a pathological liver specimen can be described on the basis of six or more adjacent fields of view with an increased ploidy.

4331 DIFFERENCES BETWEEN PLASMA AND SERUM COMPLEMENT IN PATIENTS WITH CHRONIC LIVER DISEASE. (Eng.) Inai, S.; Kitamura, H.; Fujita, T.; Kojima, J.; Nagaki, K. (Center for Adult Diseases, Higashinari-ku, Osaka 537, Japan). *Clin. Exp. Immunol.* 25(3):403-409; 1976.

Plasma and serum complement (CH50) was analyzed in 60 patients with chronic liver disease (chronic hepatitis, 23; cirrhosis, 30; and 7 with hepatic cancer) and in 19 healthy subjects. The serum and plasma were separated and the hemolytic activities of complement and its components were assayed and their protein concentrations determined. In addition, hepatitis B surface antigen (HBsAg) and antibody were assayed by the immune adherence hemagglutination method. Eight patients with cirrhosis or chronic hepatitis had very low serum CH50 but normal plasma CH50; the serum and plasma levels of the remaining patients were relatively normal. The complement profiles of the patients with abnormal sera presented markedly decreased C4 and C2 activities but normal C3T (C3-C9) activities. The results suggest that early-acting complement components had been nonspecifically activated in the eight patients with very low serum but normal plasma CH50 through the classical pathway, although the possibility exists that the C1 component in these patients was activated through unknown mechanisms during blood coagulation or by mechanisms independent of coagulation and inhibitible by EDTA. No difference was found between plasma and serum CH50 in patients with HBsAg.

4332 ANTIMITOCHONDRIAL ANTIBODIES IN CHRONIC LIVER DISEASES. (Rus.) Bondar, Z. A.; Speransky, A. I.; Podymova, S. D.; Nasonov, E. L. (I.M. Sechenov Medical Inst., Moscow, USSR). *Sov. Med.* (12):11-15; 1976.

The diagnostic importance of antimitochondrial antibodies (AMA) was studied in 100 patients with different chronic disorders of the liver (17, primary biliary cirrhosis [PBC]; 35, chronic active hepatitis [CAH]; 23, macro- and micronodular cirrhosis; 5, chronic persistent hepatitis [CPH]; 10, systemic lupus erythematosus; and 10, rheumatoid arthritis). Ten healthy donors served as controls. Each patient was investigated immunologically for antismooth muscle antibody, rheumatoid factor, and immunoglobulins G, A, and M. AMA, estimated by indirect immunofluorescence, were revealed in 15/17 patients with PBC, in 6/35 with CAH, and were absent in patients with other liver diseases, connective tissue disorders, and in the controls. In every patient with PBC, an increase in the levels of cholesterol, alkaline phosphatase, and bilirubin was noted. Hypergammaglobulinemia was more characteristic of CAH. No difference in the level of transaminases was noted. In every patient with CAH in whom AMA were found, symptoms of cholestasis were noted: i.e., an increase in cholesterol and alkaline phosphatase levels, though to a lesser degree than in PBC patients. The highest titer of AMA (1:640) was found in PBC patients and the lowest, in CAH patients. The titers of AMA did not depend upon the intensity of clinical, immunological, and biochemical findings, or upon the stage of PBC.

4333 DEMONSTRATION OF MITOCHONDRIAL ANTIBODIES IN SERA FROM PATIENTS WITH CHRONIC LIVER DISEASES REACTING WITH TWO DIFFERENT TYPES OF COMPLEMENT-FIXING ANTIGENS. (Eng.) Berg, P. A.; Binder, T. (Medizinische Universitatsklinik, Otfried-Muller-Strasse, D-74 Tubingen, W. Germany). *Minerva Gastroenterol.* 22(3):185-189; 1976.

Mitochondrial antibodies have been detected in three different types of diseases: primary biliary cirrhosis (PBC), chronic active hepatitis (CAH) or cryptogenetic cirrhosis, and in pseudolupus erythematosus (PLE), a syndrome resembling systemic lupus erythematosus and now known to be drug-induced. One hundred and thirty-seven mitochondrial antibody-positive sera were tested against PBC and PLE antigens. Out of 55 PLE sera, 54 reacted with the corresponding antigen, whereas none of the 71 sera from patients with chronic liver diseases showed any reaction with the PLE antigen. However, only 39 sera fixed complement exclusively with the PBC antigen; the other 32 had antibody that reacted equally well with the PBC and PLE antigen. All patients whose sera reacted exclusively with the PBC antigen or with the PLE antigen manifested the classical clinical, biochemical, and pathological features of PBC or PLE. The patients whose sera reacted with both antigens showed a "mixed" clinical picture of CAH and PBC. The close correlation of specific antibodies with defined clinical entities or syndromes may reflect the etiological differences among these diseases. The observation that these antibodies may disappear during remission and rise again at relapse implies that immune mechanisms play a pathogenic role and may determine the outcome of a disease.

4334 CLINICAL APPLICATIONS OF IN VITRO TESTS FOR CELL-MEDIATED IMMUNITY IN LIVER DISEASES. (Eng.) Paronetto, F.; Vernace, S. J.; Colombo, M. (Mount Sinai Sch. Medicine City Univ. New York, New York, NY 10029). *Minerva Gastroenterol.* 22(3):227-232; 1976.

Cell-mediated immunity is a determinant in the pathogenesis of acute and chronic forms of liver diseases. Several *in vitro* tests have been devised to monitor the function of different subpopulations of lymphocytes, since it has been recognized that these cells are the effector cells of cellular immune reactions. Skin tests and studies of T and B lymphocytes, migration inhibition, lymphocyte stimulation, and lymphocytotoxicity detect not only sensitization of lymphocytes, which might be of pathogenetic significance, but also may be the result of liver damage. Cytotoxogenicity of lymphocytes *in vitro* supports the hypothesis that lymphocytes play a major role in the pathogenesis of some acute and chronic forms of liver disease. Blocking factors might interfere with the immunological responses of the lymphocytes against the liver. It is not clear which technique is best suited for monitoring the alteration of cell-mediated immunity. Most likely, a combination of tests would give a more comprehensive picture of the immunological status of the patient. Though not easy to perform, these tests can be of value in the prediction of the clinical outcome of patients with liver diseases.

4335 CHANGES IN THE ACID-BASE BALANCE DUE TO TREATMENT CONSISTING OF EXTRACTION, CONCENTRATION AND REINFUSION OF ASCITIC LIQUID IN LIVER CIRRHOSIS. (Ita.) Novarini, A.; Guariglia, A.; Bruschi, G.; Borghi, L.; Canali, M.; Ghinelli, F.; *et al.* (Istituto di Semeiotica Medica, Universita di Parma, 43100 Parma, Italy). *Ateneo Parmense [Acta Biomed.]* 47(1):5-13; 1976.

Changes in the acid-base metabolism of nine patients with cirrhosis of the liver and ascites were studied by determining blood electrolytes and acid-base status (sodium, potassium, osmolarity, chloride), and urine (volume/min, sodium, potassium, pH, titratable acidity, NH^{4+}). The acid-base balance parameters (pH, pCO_2, H_2CO_3, HCO_3^-, HCO_3^-/H_2CO_3) were determined in arterial blood and in ascitic fluid and its reinfused concentrate. The determinations were made before, during, and after infusion of concentrated ascites fluid obtained by an extraction-concentration reinfusion procedure. The renal function, expressed by the glomerular filtration rate (GFR) and renal plasma flow (RPF), was determined only before and after the treatment. Before treatment, the acid-base balance parameters showed decreased pCO_2 (33.6 ± 3.5 mm Hg), which was attributed to hyperventilation. The renal function was decreased (GFR=72 ml/min; RPF=472 ml/min) without reaching the limits of renal insufficiency. All the other parameters were normal. The blood and acid-base parameters during treatment were not significantly different from those before. The pH of the reinfused concentrated ascitic fluid was alkaline (7.57 ± 0.004), and the pCO_2 was significantly decreased (20.7 ± 1.1 mm Hg). All parameters determined after the treatment were comparable to those found before. The results imply that the treatment did not determine any significant variations in the acid-base balance; a significant loss of CO_2 was noted in the concentrated ascitic fluid.

4336 OUTCOME OF CHRONIC CHOLECYSTITIS LESIONS OF THE LIVER (MECHANISMS OF DEVELOPMENT OF BILIARY CIRRHOSIS). (Rus.) Bluyger, A. F.; Maksimova, L. A.; Kartashova, O. Ya.; Briedis, L. P. (Hepatological Center, Ministry Health, Latvian SSR, USSR). *Ter. Arkh.* 48(9):20-24; 1976.

The results of follow-up examination of 20 patients (all women, age 33-65 yr) with primary biliary cirrhosis (PBC) due to chronic intrahepatic cholestasis and of 49 patients with extrahepatic cholestasis (20 men, 27 women, aged 26-70 yr) are presented. Thirty of the patients with extrahepatic cholestasis also had acute obstructive jaundice, and 19 had chronic mechanical blockade of the bile ducts, which caused secondary biliary cirrhosis (SBC). The patients with both destructive cholangitis and PBC showed reduced alanine aminotransferase activity, and elevated cholesterol and β-lipoprotein levels. The patients with SBC had more pronounced hypergammaglobulinemia and less pronounced hypercholesteremia and β-liporpoteinemia, which may be due to decompensation of liver function.

4337 PORTAL VENOUS AND SYSTEMIC ENDOTOXAEMIA IN PATIENTS WITHOUT LIVER DISEASE AND SYSTEMIC ENDOTOXAEMIA IN PATIENTS WITH CIRRHOSIS. (Eng.) Prytz, H.; Holst-Christensen, J.; Korner, B.; Liehr, H. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Scand. J. Gastroenterol.* 11(8):857-863; 1976.

Portal blood in man was investigated to determine whether it contains endotoxin and/or viable bacteria and whether the liver acts as a filter of these substances. In cirrhosis, the clinical significance of systemic endotoxemia for clinical and laboratory findings was also evaluated. By means of the *limulus* gelation test, portal venous blood from 21 patients without parenchymal liver disease and arterial blood from 21 patients without parenchymal liver disease and 31 patients with cirrhosis were examined for endotoxin. Portal venous endotoxemia was found in 9 of 21 samples and systemic endotoxemia was found in 2 of 21 samples from patients without liver disease. Systemic endotoxemia in cirrhosis occurred with a frequency of 15/31. No relation to gram-negative bacteremia was found. Higher levels of *Escherichia coli* O antibodies were found in endotoxin-positive than were found in endotoxin-negative patients with cirrhosis, which supports the view that the *limulus* gelation test specifically detects endotoxin. This suggests that endotoxin is a normal constituent of the portal venous blood in man. The normal human liver effectively clears endotoxin from portal venous blood. This effect is diminished in cirrhosis, probably due to decreased phagocytic function in the liver. The increased humoral immune response in cirrhosis may be related to spillover of endotoxin from the liver.

4338 A COMPARATIVE STUDY OF CIRRHOSIS WITH AND WITHOUT PRIMARY CANCER OF THE LIVER.

(Fre.) Gislon, J.; Barge, J.; Feldmann, G. (Unite de Recherches de Physiopathologie Hepatique, INSERM, Hopital Beaujon, F 92110 Clichy, France). *Arch. Fr. Mal. App. Dig.* 65(5):369-378; 1976.

A necropsy study of 266 patients who died of liver cirrhosis (LCi) over a 4-yr period revealed that 44 (42 men, 2 women) had primary liver cancer (LCa), whereas 222 (122 men, 100 women) did not. A histological study of the 42 men of the LCa group showed that in 41 (group I), the LCi was a macronodular type comprised of irregular nodules. This type was also seen in 87 men without primary LCa (group II). The patients with primary LCa had statistically lower liver weights than those with LCi alone. Of the group I patients, 19 had dissemination of the cancer, 40 had a hepatocarcinoma, and 1, a cholangiocarcinoma. Eight of the group II patients had portal thrombosis. Both groups showed the same clinical signs, except that group I patients had significant weight loss, pain in the right hypochondrium, and a statistically significant rise in alkaline phosphatase and ESR values. Otherwise, no etiological differences were noted between both groups. The 2-yr survival of group I patients was only 20%, compared with 51% for group II patients. The mean age of death was 63 and 55 yr for groups I and II patients, resp. Fatal infections were more predominant in the latter group, but fatal hypoglycemia was more frequent in group I patients. The findings suggest that primary cancer is a late complication of cirrhosis, and indicate that men, 60 yr of age and older, with macronodular cirrhosis should be closely monitored for the development of primary liver cancer.

4339 THE CIRRHOTIC PATIENT AND PORTACAVAL SHUNT IN 1977.

(Fre.) Huet, P. M.; Marleau, D.; Lavoie, P.; Tanguay, S.; Viallet, A. (Hopital Saint-Luc et Universite de Montreal, Canada). *Union Med. Can.* 106(5):644-648; 1977.

The prognostic value of the evaluation of the functional portal blood supply to the liver by indocyanine green extraction (IGE), alone or with arterialization of the portal vein (10 patients), was studied in 30 cirrhotic patients, 20 of whom had a therapeutic portacaval shunt. All patients had hemodynamic studies, and all presented severe portal hypertension. A great variation in the IGE was noted ranging from a minimum of 3.3% to a maximum of 43.8%. Of the 20 patients who only had a portacaval shunt, 19 were followed from 1-50 months. Seven patients developed hepatic encephalopathy, and they had preoperative IGE values above 20% (average, 33.7%). No encephalopathy was noted in 12 patients who had IGE's below 20%. Of nine patients who died, only one death was attributed to rapidly progressive hepatic insufficiency. Of the 10 patients in the arterialization group, 7 were followed from 12-50 months. No encephalopathy or hepatic insufficiency developed in this group of patients. Three patients had a low IGE and consequently a markedly diminished functional portal flow, whereas four patients had a mean IGE of 31.9%. The preliminary results suggest that tolerance of a portacaval shunt procedure is better in patients with markedly depressed functional portal blood flow and that patients with slightly decreased portal blood supply might benefit from arterialization of the portal vein.

4340 RESULTS OF PORTACAVAL SHUNT WITH ARTERIALIZATION OF THE LIVER.

(Ger.) Matzander, U. (Chirurgische Klinik des Friedrich-Ebert-Krankenhauses, Sachsenring 1, D-2350 Neumunster, W. Germany) *Langenbecks Arch. Chir.* 342:145-151; 1976.

Arterialization of the liver with a portacaval shunt was performed in 82 cirrhotic patients with portal hypertension. Arterialization was done via the vena umbilicalis. The mortality during the first 4 weeks after operation was 19%. Of 35 patients subjected to arterialization after their first varicial bleeding, 16 survived 5 yr, 12/16 for >6 yr, 4/12 for 7 yr, and 2/4 for 8 yr. The patients had a marked drop in ammonia level in the peripheral blood and in BSP retention. Most patients became wel enough to resume their occupations. Excellent results were also obtained in a 55-yr-old man who developed encephalopathy following portacaval anastomosis.

4341 ORAL CHOLATE TOLERANCE TEST--AN APPLICATION OF THE RADIOIMMUNOASSAY OF SERUM CHOLIC ACID [Abstract].

(Eng.) Matern, S.; Haag, M.; Gerok, W. (Medizinische Universitatsklinik, Freiburg im Breisgau, W. Germany). *Digestion* 14(5/6):534; 1976.

4342 KINETIC STUDIES OF THE ROSE BENGAL TRANSPORT IN CIRRHOSIS OF THE LIVER [Abstract]. (Eng.) Pirotte, J. (Hopital de Baviere, Liege, Belgium). *Digestion* 14(5/6):483-484; 1976.

4343 RECTAL ^{13}N-AMMONIA TEST (^{13}N-LIVER/HEART RATIO), HEPATIC SINUSOIDAL PRESSURE AND PREVAILING PORTAL FLOW DIRECTION IN CIRRHOSIS OF THE LIVER [Abstract]. (Eng.) Hazenberg, H. J. A.; Gips, C. H.; Beekhuis, H.; Kruizinga, K. (Univ. Hosp., Groningen, Netherlands). *Digestion* 14(5/6): 518; 1976.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

4353 RADIOLOGICAL AND SURGICAL COMPARISONS IN THE STUDY OF THE BILIARY TRACT. CHOLANGIOGRAPHY BY ONE-HOUR PERFUSION: PEROPERATIVE CHOLANGIOGRAPHY. (Fre.) Dayras, M.; Labrune, M.; Larrieu, H. (Service de Radiologie, Hopital Antoine-Beclere, 154 ave. de la Porte-de-Trivaux, F 92140 Clamart, France). *Ann. Radiol. (Paris)* 19(8):759-764; 1976.

Pre- and peroperative radiographs were compared in 85 cholecystectomized patients. All preoperative radiographs were made after a 1-hr i.v. perfusion of radiopaque material, and a radiomanometric technique was used peroperatively. Peroperative cholangiographs showed the bile ducts more clearly, especially the intrahepatic duct. In 50/85 cases the pre- and peroperative findings were in good agreement. Most discrepancies in the remaining 35 cases arose because the i.v. cholangiographs failed to demonstrate lithiasis of the common bile duct.

4354 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY USING A FINE NEEDLE. 84 CASES. (Fre.) Bory, R. M.; Dubreuil, A.; Trepo, C. (Hopital

Edouard-Herriot, Place d'Arsonval, F 69374 Lyon Cedex 2, France). *Nouv. Presse Med.* 6(10):829-832; 1977.

The results of transhepatic percutaneous cholangiography (TCP) in 84 patients (39 with obstructive jaundice and 45 with suspected nonjaundiced biliary disease) are reported. The use of a fine needle caused a minimum of trauma and hemorrhage; only one case required surgery for a hemoperitoneum. The bile ducts were clearly visible in 67% of cases, with 100% of dilated ducts and 48% of normal ducts rendered opaque. The procedure was well-tolerated, and no reactions to the contrast medium or infectious complications occurred. TCP is recommended when jaundice is present or when cholecystography or cholangiography fails to opacify the ducts. When a hemorrhagic risk is present, percutaneous transjugular cholangiography or retrograde perendoscopic cholangiography is recommended.

4355 EVALUATION OF CHOLERETIC ACTIVITY OF DIHYDROXYDIBUTYL ETHER.

(Eng.) Fici, F.; Camarri, E.; Galluzzi, F.; Bagnoli, M. (Istituto Lusofarmaco, Milan, Italy). *Curr. Ther. Res.* 20(6): 772-793; 1976.

Biliary excretion induced by single doses of dihydroxydibutyl ether (DHDE) was evaluated quantitatively and qualitatively in 14 hospitalized patients without hepatobiliary or renal diseases. A 35% solution of DHDE was administered by duodenal tube in single doses of 300 mg (4 patients), 450 mg (5), and 750 mg (5). All dose levels produced a significant ($p<0.01$) increase in biliary flow, with increases of 38.8%, 70.4%, and 67.0%, resp., at 40-50 min. All DHDE doses also produced a significant ($p<0.01$) increase in the output of all solid components of the bile. Biliary acid outputs rose, with maximum percent increases of 109.2%, 164.1%, and 181.2%, resp., for the three doses. Cholesterol and phospholipid excretion rose also, with individual maximum increases of 92.6%, 172.3%, and 174.7% for cholesterol and 110.5%, 219.9%, and 150.9% for phospholipids, resp., for the three doses. Bilirubin output exhibited similar increases: 100.6% 148.7%, and 144.5% for the three doses, resp. Peak excretion of all solid components occurred 40 min after the administration of the 300-mg dose, with output decreasing gradually thereafter, although never returning to the initial values. Peak excretion of solid components occurred at 50-60 min with the 450-mg dose, was followed by an early decrease, and was at all times significantly ($p<0.01$) higher than the basal values. With the 750-mg dose, the peak excretion of solid components occurred after 40 min, except for the biliary acid output; this peak was followed by a declining phase and then a second increasing phase. The effects of DHDE are not dose-dependent; the increase in the output of solid components that occurred when the dose was raised from 450 mg to 750 mg was not proportional to the significant ($p<0.01$) increase that occurred when the dose was raised from 300 mg to 450 mg. DHDE can be classed as a true choleretic.

4356 INVESTIGATIONS OF THE CHOLERETIC ACTION OF FEBUPROL ON HEALTHY TEST SUBJECTS

(Ger. Wolf, Chr.; Ritter, U.; Zschocke, R.; Weinert, W. (I. Medizinische Klinik der Medizinischen Hochschule Lubeck, Kronsdorfer Allee, D-2400, Lubeck, W. Germany *Munch. Med. Wochenschr.* 118(40):1285-1288; 1977.

The choleretic effect of Febuprol (FB, 3-butoxy-1-phenoxypropanol-2, 50-200 mg) was studied in 18 healthy volunteers with the Bartelheimer double balloon. On three different test days, each patient received 50, 100, or 200 mg of FB as an emulsion in distilled water intraduodenally. Six subjects acted as controls and were given distilled water only (placebo). FB induced a dose-dependent, statistically significant increase in total bile in comparison with placebo-treated subjects. An absolute increase of bile acids, total cholesterol, phospholipids, and total bilirubin was ascertained in the FB-treated group. The concentrations of these constituents were greater in subjects given the 100-mg dose. The lithogenic index in the FB-treated subjects showed no significant change.

4357 CIRCULATING TISSUE ANTIGENS. III. IDENTIFICATION AND CHARACTERIZATION OF ANTIGENS OF LIMITED AND WIDE BODY DISTRIBUTION IN HUMAN GALL BLADDER BILE. PRESENCE IN SERUM OF PATIENTS WITH ACUTE HEPATITIS.

(Eng.) Espinosa, E. (Dept. Pathology, Univ. Louisville Sch. Medicine, Louisville, KY 40201). *Clin. Exp. Immunol.* 25(3):410-417; 1976.

Antigens specific to bile and antigens shared by bil and other tissues were investigated and characterized. Human gallbladder bile and liver, kidney, cardiac muscle, and skeletal muscle tissues were obtained a few hours after death from eight patients considered to be normal at autopsy. Pig, dog, cat, guinea pig, and Rhesus monkey biles were obtained shortly after sacrifice of the animals. Rabbit antisera to the bile and to saline extracts of the tissues were prepared. The bile samples, when tested with the antisera by double immunodiffusion, all shared antigens BT-1, BT-2, and BT-3, and half the samples shared an antigen designated BA that was unrelated to BT-1. Antigens BT-2 and BT-3 were unrelated to BT-1 or BA. Kidney was found to share BT-1, and liver was found to share BT-2 and BT-3, with all the bile samples. All four antigens separated from one another in immunoelectrophoresis and by Sephadex G-200 gel filtration, the order of elution from the column being BT-1, BT-3, BA, and BT-2. Lyophilized preparations of various tissues and body fluids were tested for their ability to abolish the precipitin lines in immunodiffusion experiments by absorbing the antibodies from the antisera. The results indicated that BT-1 is present in bile, kidney, and urine. BT-2 and BT-3 are mainly found in liver, kidney, lung, and bile. BA was found in half the bile samples and in the saliva of three of five normal subjects screened. Species specificity was studied by absorbing antisera with biles from variou mammals. Absorption with human bile abolished all antigen reactions, except when the absorbant was one of the samples in which BA did not occur. Absorptio with pig, dog, cat, and guinea pig biles did not alter any of the lines of precipitation. Only the BA reaction was abolished by absorption with Rhesus monkey bile. The sensitivity of the antigens to pronase, heating, and variations in pH were investigated. The sera of 33 patients and 48 normal blood donors were examined by double immunodiffusion for the presence of bile antigens. BT-1 and BA were not detected in any samples, BT-2 and BT-3 were detected in most patients with acute hepatitis, but not in any other subjects. The demonstration of cell-mediated immune response to a protein fraction of human bile from patients with primary biliary cirrhosis and chronic active hepatitis suggests that bile antigens may be related to autoimmune liver disease.

4358 RADIOLOGICAL DIAGNOSIS OF BOUVERET'S SYNDROME.

(Fre.) Felix, M.; Burelle, H.; Clement, J. P.; Devin, R. (Hopital Sainte-Marguerite, 270, Blvd. Sainte-Marguerite, F. 13274, Marseille, France). *J. Radiol. Electrol. Med. Nucl.* 58(4): 315-318; 1977.

The diagnosis and treatment of Bouveret's syndrome (a rare form of biliary fistula) in an 81-yr-old man are presented. Upon admission, the patient complained of slight hematemesis. X-ray examination revealed a gallstone obstructing the proximal duodenum. A barium gastroduodenal transit study showed a large, rounded, regular obstruction of the duodenal bulb surrounded by a fine circle of barium and occupying almost the entire duodenal bulb. Laparotomy disclosed multiple calculi in the gallbladder. A large stone (2.7 cm in diameter) was removed by means of a limited gastrostomy. Gastroduodenal transit studies provide the most diagnostic information for unusual biliary fistulas.

4359 THE CONTRIBUTION OF DUODENOSCOPY IN THE DIAGNOSIS OF TUMORS OF THE PAPILLA.

(Fre.) Cremer, M.; Hermanus, A.; Dony, A.; Deltenre, M.; Toussaint, J.; Govaerts, J. P.; Peeters, J. P. (No affiliation given). *Bordeaux Med.* 9(18):1433-1439; 1976.

Of a series of 19 papillary tumors, 17 were discovered by endoscopic cholangiowirsungography of 579 patients with obstructive icterus, while 2 were found out of a total of 4,972 duodenoscopies. Carcinoma of Vater's ampulla was present in 10 patients (average 71.3 yr; 8 men, 2 women), 9 of which had obstructive icterus. The bile duct and hepatic ducts were always dilated, and obstructive pancreatitis occurred in two cases. Local resections and reimplantation of the hepatic and pancreatic duct were performed in seven cases, and bilio-digestive derivations in three cases. Benign tumors were found in six patients (average 68.3 yr; 5 men, 1 woman); the symptoms of these tumors were similar but not as severe as with carcinomas, since the tumors were generally much smaller. Local resections were done in three cases and derivations in two cases. Endoscopy was diagnostic for tumors in all patients, but endoscopic biopsy was of minimal value in characterizing the tumors.

4360 A RARE FORM OF CARCINOMA OF THE COMMON BILE DUCT: PAPILLARY CARCINOMA

(Fre.) Malvy, P.; Le Neel, J. C.; Nomballais, M. F.; Le Borgne, J.; Visset, J. (U.E.R. de Medecine 1, rue Gaston Veil, 44035, Nantes, France). *J. Chir. (Paris)* 112(1/2):15-24; 1976.

Papillary carcinomas, which represent only 5% of all common bile duct carcinomas, were observed in four patients. Diagnosis was difficult, due to the long prodromal phase and the nonspecific symptoms, which included attacks of cholangitis, subclinical jaundice, and postprandial epigastric pains. Surgical intervention resulted almost always in the macroscopic diagnosis of the disease, which was confirmed microscopically. The papillary carcinomas had a villous appearance and consisted of fine coalescent fringes. Cellular abnormalities and atypical mitoses were frequent. Since the tumor evolves very slowly, even palliative surgery can result in long term survival. Radical resections are recommended for patients in good general health, since local recurrences are very high.

4361 THE CONTENT OF BILIARY CALCULI AND SOME POSSIBLE CAUSES OF THEIR FORMATION.

(Rus.) Mironenko, G. A.; Iurgenson, G. A. (Medical Inst. Chita, USSR). *Vestn. Khir.* 117(12):47-49; 1976.

A total of 135 biliary calculi from 120 operated patients were studied visually and with infrared spectrophotometry. Four groups of calculi were differentiated according to their biochemical content: G1, cholesterol containing less than 1% of metal and phosphorus; G2, metalocholesterol containing 20-30% magnesium and calcium; G3, cholesterolphosphatide with high concentrations (ranging from 2-5%) of metals, especially calcium, magnesium, sodium, and phosphorus; and G4, phosphatide-protein with high concentrations of iron, sodium, manganese, calcium, magnesium, copper, and unusually high concentration of nitrogen (5.52%). Interaction between metallic elements in the formation of biliary calculi was revealed by correlative analysis. Two biochemical processes leading to calculi formation are suggested. The precipitation of cholesterol from the bile and blood may be explained by interaction between aluminum and iron resulting in substitution of Fe^{+++} for Al^{+++}. A second possible mechanism is a disturbance of the metabolism of phosphorus and sodium, as related to the increase of phosphorus concentration in the blood serum of patients with cholelithiasis.

4362 EXAMINATION OF THE SURFACE OF GALLSTONES AND THE FRACTURED CROSS SECTIONS BY INCIDENT LIGHT MICROSCOPY AND SCANNING ELECTRON MICROSCOPY.

(Ger.) Cesnik, H.; Mitsche, R.; Strunz, K. (Chirurgische Abteilung des Landeskrankenhauses Leoben, A-8700 Leoben, Austria). *Langenbecks Arch. Chir.* 343(2):153-160; 1977.

The surfaces and fractured cross sections of gallstones were examined by incident light microscopy (ILM), scanning electron microscopy (SEM), elemental microanalysis (EM), and x-ray crystallography (XRC). ILM revealed five types of gallstones consisting of three basic structural layers: a central nucleus, a radially structured middle layer, and a fine crystalline outer shell. The presence or absence of the latter two layers differentiates the five types. Basically, flat and globular types were demonstrated by SEM. The globular element always belonged to the nucleus; the flat, crystalline element to the outer layers. EM revealed calcium in the nucleus, radial structure, and inner layers but not in the outer white layers. Iodine could also be detected in certain stones. White crystal formation was apparent at sites of fracture. XRC showed that the outer layer and transcrystalline inner layer were identical and appeared to be made up of pure cholesterol. Changes in the structure of gallstones are most likely due to a physical or chemical condition during their development.

4363 BILE ACID ALTERATIONS IN PATIENTS WITH CHOLESTEROL GALLSTONES. (Eng.) McDougall, R. M.; Walker, K.; Thurston, O. G. (Univ. Alberta Hosp., Edmonton, Alberta, Canada T6G 2G3). *J. Surg. Res.* 21(4):233-237; 1976.

The proportions of individual bile acids in gallbladder bile were studied in eight patients with cholesterol gallstones and in six controls undergoing laparotomy for other upper abdominal conditions. The gallstone patients all had functioning gallbladders. The eight patients had bile supersaturated with cholesterol, while the control subjects had unsaturated bile. The proportion of deoxycholic acid (DCA) in the bile acid pool was significantly higher in the gallstone patients in comparison with controls (gallstone mean=30% ± 3.9%, control mean= 18 ± 2.5%, $p<0.05$). The proportions of cholic acid and chenodeoxycholic acid in gallstone patients and controls were not significantly different, although a possible trend was observed with cholic acid, where the mean was lower in the gallstone patients. Since DCA is formed in the colon by bacterial action on cholic acid, the results suggest that the colonic phase of the enterohepatic circulation is altered in patients with cholesterol gallstones.

4364 THE TREATMENT OF GALLSTONES WITH CHENODEOXYCHOLIC ACID. (Fre.) Dhumeaux, D.; Metreau, J. M. (Service d'Hepato-gastroenterologie et Unite de Recherches INSERM U-99, Hopital Henri-Mondor, F94010 Creteil, France). *Rev. Medecine* 17(31):1641-1648; 1976.

The most common form of cholelithiasis is caused by an excessive secretion of cholesterol, causing an imbalance in the ratio of cholesterol:bile salts: phospholipids in the bile. This excess cholesterol cannot be maintained in solution and is precipitated as gallstones. The prolonged oral administration of 15 mg/kg/day of chenodeoxycholic acid can reduce the cholesterol content of bile and dissolve calculi over a period of 6 months to 2 yr in 40-65% of cases. The calculi must be radiotranslucent and the gallbladder functional for the treatment to succeed. A low-dose, intermittent maintenance program should be helpful in preventing recurrences. Hepatic toxicity of the drug appears to be low, but long term effects cannot be excluded. It is suggested that treatment with chenodeoxycholic acid be limited to those patients who refuse surgery or are high surgical risks.

4365 THERAPEUTIC EFFECT OF THE CHOLAGOGUE UROCHOLESANE IN CHRONIC CHOLECYSTITIS PATIENTS. (Rus.) Nemialkovskii, I. B. (Ivano-Frankovsk Medical Inst., Ivano-Frankovsk, USSR). *Vrach. Delo* (12):76-78; 1976.

The effect of the cholagogue, urocholesane (UCS) on the clinical and metabolic function of the liver and biochemical analysis of the bile was studied in 25 patients with chronic cholecystitis. They received UCS (exact dosage not given) before meals together with a controlled diet, antihistamines, and vitamins. The results were compared with 38 untreated patients (control group). In general, side-effects were absent or minor (mouth odors). In most patients, UCS significantly decreased the pain, which was completely eliminated in five patients. The intake of UCS for 15-18 days had a favorable influence on intestinal and biliary diarrhea. In 15/25 patients, the activity of the intestine was normalized. UCS had a positive effect on the biochemical structure of both B and C bile portions. No difference in the quantity of the bile secreted by the liver was found, but fatty acid concentrations were increased (B portion from 1691.5 ± 337.2 to 2,903.0 ± 471.3 mg%, p=5%; C-portion from 518.5 ± 221.5 to 1,697.0 ± 507 mg%, p<5%). No large difference in the concentration of cholesterol was noted. Bilirubin in the C-portion of bile was increased twofold of the initial value of 1.68 ± 0.38 mg%. The results suggest that UCS significantly decreases lithogenesis of the bile and increases its colloidal stability. Use of UCS for chronic cholecystitis or gallstone disease, and other chronic diseases of the liver characterized by secretory liver deficiency and intracellular cholestasis is recommended since UCS does not increase the amount of the bile, it should be given together with hydrocholeretics.

4366 EXTRAHEPATIC BILIARY LITHIASIS IN CHILDREN. RESULTS OF A MULTICENTER INQUIRY (100 CASES). (Fre.) Fortier-Beaulieu, M.; Battin, J.; Auzerie, J.; Mage, K. (Service de Radio-Pediatrie, Hopital Herold, 7, place Rhin-et-Danube, F 75935, Paris Cedex 19, France). *Ann. Radiol. (Paris)* 19(5): 487-493; 1976.

The results of a multicenter inquiry on 100 childhood cases of biliary lithiasis (BL) are reported. The most frequent symptoms were abdominal pain, vomiting, icteric episodes, and diarrhea. BL was discovered by simple radiology of the abdomen (40), urography (11), p.o. or i.v. cholecystography (25),

ɔperation (14) or postoperative cholangiography
, and other various procedures (8). According
the diagnostic modality, the calculi were located
the secondary bile duct in 92 patients and in the
n bile duct in 19. The etiology of BL could be
ced in one-half of the cases: 24 patients had
ɔlytic anemias, 5 hepatic pathologies, 1 a cal-
ied bile syndrome, 11 malformations of the bile
ts, 5 an ileal resection, and 4 had BL and intes-
al pathology. Treatment of BL is essentially
gical. Therapy with triglycerides and chole-
ramine is recommended postoperatively.

7 DIAGNOSTIC TRAPS AND MANAGEMENT OF RADIO-INVISIBLE BILIARY LITHIASIS. (Fre.)

an, L.; Cherif-Zahar, K.; Lepage, B.; Bories-
au, A. (Service de Chirurgie D, Clinique Saint-
:les, 34059 Montpellier, France). *J. Chir.*
ris) 111(4):431-442; 1977.

iical and biological parameters leading to a de-
ion to surgically treat biliary microlithiasis
e., radio-invisible biliary lithiasis) are re-
wed, and four case histories of cholecystecto-
ed patients with misleading initial findings
g., normal transvesicular bilography, cholangio-
phy-tomography, and the absence of arterial or
cification anomalies) are presented. Symptoma-
ogy associated with acute pancreatitis, hepatic
ic, acute papillary obstruction, transitory ob-
uction of the vesicular infundibulum, and chole-
tic, pancreatic, and duodenal duct syndrome
considered. Situations requiring exploration
the major bile duct (e.g., where the presence
calculi is uncertain) with respect to probable
dings, radiomanometry, and direct examination
presented. Preference for the term radio-
isible biliary lithiasis (i.e., biliary micro-
iiasis) is expressed, since the parameters are
itical, but the former is more reflective of
diagnostic difficulties involved. It is rec-
ended that medically screened patients with
urrent pancreatitis be subjected to surgical bil-
y exploration, and in cases of perceptible lithi-
s or where the gallbladder bile contains mud,
ris, sand, or cholesterol spheroids, that chole-
tectomy be performed.

3 ON THE MECHANISM OF PRODUCTION OF THE "PORCELAIN GALLBLADDER." (Rum.)

Brinzeu,
Georgescu, L.; Mocanu, N.; Mogoscanu, M. (Clin-
I chirurgie, Timisoara, Rumania). *Chirurgia*
charest) 25(3):183-187; 1976.

culous cholecystitis with hydrops of the gall-
dder was diagnosed in a 50-yr-old woman who had
an acute biliary colic 12 yr earlier. Radio-
phy showed the typical picture of porcelain
lbladder. The histological examination of the
irpated gallbladder revealed three local patho-
etic factors that led to porcelain gallbladder:
onic entrapment of a stone in the bladder neck
h obliteration of the cystic duct, chronic in-
mmation of the wall of the gallblader, and
hemia of the entire gallbladder due to oblitera-
tion of the cystic artery. The coincidence of these three factors in the same patient is exceptional, which explains the rarity of this complication of cholelithiasis.

4369 A CONTROLLED STUDY OF THE ACTION OF PINAVERIUM BROMIDE ON BILIARY DYSKINESIS.

(Fre.) Darnis, F. (Hopital Saint-Antoine, 75012 Paris, France). *Ann. Gastroenterol. Hepatol.* 13(2): 177-184; 1977.

A biphasic analysis of the effect of Pinavarium bromide on two groups of patients with biliary dyskinesis (BD) is presented. Group I was comprised of 2 men and 18 women (mean age, 46 ± 15 yr). Group II was comprised of 5 men and 15 women (mean age, 48 ± 12 yr). Patients with malignant digestive disease and non-BD related pain were excluded from the study. Pinaverium bromide, 50 mg, was given 0.5 hr before meals (150 mg/day) in the form of red (phase I) or blue (phase II) capsules. In phase I, group I patients were given active substance; group II patients were given placebo for 7 days (or if inefficacious, discontinued after 4 days and started on phase II). In phase II, both group I and group II were given active substance for 7 days. The parameters of therapeutic activity were: abdominal pain (spontaneous or provoked), migrain, nausea, vomiting, diarrhea, constipation, and dyspepsia. Results were judged good if abdominal pain and related symptomatology disappeared, moderate if abdominal pain diminished and related symptomatology was ameliorated, and null if pain and symptomatology persisted. Treatment was judged ineffective after 4 or 7 days in 7 patients on active substance, and 15 patients on placebo. Indices of medicine tolerance were: cardiac frequency; arterial pressure, and anticholinergic symptomatology. The active substance was more effective than placebo ($p<.05$), and early discontinuence of treatment was higher in the placebo group ($p<.02$). Clinical tolerance of the drug was good and no anticholinergic side-effect was noted.

4370 THE SO-CALLED "WHITE BILE:" A CLINICAL-EXPERIMENTAL INVESTIGATION. (Rus.)

Makokha, N. S.; Zykov, Iu. A.; Budanov, V. A.; Jazik, S. I. (Omsk Medical Inst., Omsk, USSR). *Vestn. Khir.* 116(8):22-24; 1976.

The characteristics of the so-called "white bile," observed in obstructive jaundice of various etiologies are described based on 37 clinical cases and experimental findings in 20 dogs. From 1965 to 1974, 205 operations for extrahepatic obstruction were carried out, and "white bile" was found in 37 patients (19 men, and 18 women). In 35 patients, the "white bile" was was viscous and slightly opalescent; in 2 patients it was a greenish liquid with flakes of fibrin. Differences in "white bile," related to the duration of obstructive jaundice, were not found. In the experimental study in 20 dogs, obstructive jaundice was provoked by ligation and incision of the common bile duct. In nine dogs, autopsy revealed transparent, viscous, slightly opalescent fluid in the gallbladder and hepatic ducts (dogs were killed 14, 18, 30, and 40 days after ligation). In another series of experiments, a fistula was applied to 11 dogs, and the gallbladder was excluded from digestion by ligation of the cystic duct. In 7/11 dogs the common bile duct was ligated in addition. In three dogs of this series, viscous, slightly opalescent fluid was secreted for 1.5-2 months; in one dog, the secretion was discharged for 6 months. The amount of secretion depended on the weight of dogs and fluctuated from 2 to 10 ml/24 hr. On the first day after surgery, secretion was colored by bile; on the 3-5th day, bile became transparent, viscous, and opalescent. It was concluded that "white bile" is a colorless secretion of bile ducts and gallbladder mucous membrane found more often in complete obstruction of the extrahepatic bile ducts when duration of the jaundice is not less than 10-14 days.

4371 MALACOPLASIA OF THE CYSTIC DUCT. (Fre.) Sahel, J.; Scheiner, C.; Lebreuil, G.; Sarles, H. (Hopital Sainte-Marguerite, F 13009 Marseille, France). *Arch. Fr. Mal. App. Dig.* 65(8): 585-590; 1976.

A rare case of malacoplasia of the cystic duct occurred in a 7.5-yr-old boy. The patient had repeated painful biliary crises accompanied by fever and eosinophilia. A parasitic infection was suspected, since the patient had recently resided in North Africa, but this could never be demonstrated. He was treated medically for 3 yr with only partial and transitory success. Cholangiographic studies showed a normal common bile duct, but the gallbladder could not be opacified. Surgical intervention showed a histiocytic cholecystitis without lithiasis and a villous papilloma that obstructed the cystic duct. After cholecystectomy, the patient recovered fully and the eosinophilia gradually disappeared.

GENERAL

4388 BACTEREMIA AFTER UPPER GASTROINTESTINAL ENDOSCOPY. (Eng.) Baltch, A. L.; Buhac, I.; Agrawal, A.; O'Connor, P.; Bram, M.; Malatino, E. (Veterans Admin. Hosp., 113 Holland Ave., Albany, NY 12208). *Arch. Intern. Med.* 137(5):594-597; 1977.

The occurrence, persistence, and possible significance of bacteremia associated with upper gastrointestinal endoscopy were determined, and two commonly used bacteriologic blood culture media were compared in the detection of bacteremia in these patients. During 24 months, 200 upper gastrointestinal endoscopies were performed on 193 patients. Blood cultures were obtained before and 5 and 30 min after the procedure using thiol (50 ml) and trypticase soy broth (100 ml) media. The mean endoscopic time was 34 min. Sixteen patients developed bacteremia (8%). Twelve groups of microorganisms were detected in positive blood cultures: *Streptococcus* (5 species), *Lactobacillus* sp., *Veillonella alcalescens*, *Staphylococcus aureus*, *S. epidermis*, *Propionibacterium acnes*, *Corynebacterium acnes*, and *Bacillus subtilis*. Seven patients had positive blood cultures at 5 and 30 min, eight at 5 min, and one at 30 min only. There was no clear correlation of bacteremia with the age or previous history of the patient, biopsy, active bleeding, endoscopic time, or findings. A follow-up study of all patients for 6 months to 2 yr indicated no complications related to endoscopy and/or bacteremia.

4389 ARTICULAR MANIFESTATIONS OF CARCINOID TUMORS OF THE DIGESTIVE TRACT. (Fre.) Solnica, J. (Hotel-Dieu, F 76038 Rouen Cedex, France). *Rev. Rhum.* 43(10):591-594; 1976.

The rare occurrence of joint manifestations of carcinoid tumors (CT) of the digestive tract are reviewed. These manifestations resemble rheumatic disease and include morning stiffness, joint inflammation, elevated erythrocyte sedimentation rate, and hyperuricemia. X-ray examination has also revealed bands of osteoporosis and evidence of joint lesions. Arthralgias fluctuate during evolution of CT. Radiological signs of tumor are present in two-thirds of the CT cases, appearing either as a benign tumor of the stomach or a malignant tumor of the colon. Metastases are frequent, especially in CT of the small intestine. Increased urinary excretion of 5-hydroxyindoleacetic acid (>25 mg/24 hr-1,200 mg/24 hr in metastatic tumor) is a biological sign of CT. Etiologically, CT are equally distributed among the sexes, and they are particularly prevalent between the ages of 60 and 70 yr. The causes of arthropathies of CT are unknown although bradykinin, prostaglandins, collagen, and tryptophan have all been implicated.

4390 ESOPHAGEAL LOCALIZATIONS OF DARIER'S DISEASE: RADIOLOGICAL DESCRIPTION OF FOUR CASES. (Fre.) Larregue, M.; Katz, M.; Gasquet, C.; Lansmann, M. (Centre hospitalier regional de l'Hotel-Dieu, Poitiers, France). *Union Med. Can.* 106(1): 50-54; 1977.

Esophageal localizations of Darier's disease were detected by radiography in four patients. All four patients presented with mucosal lesions of the esophagus (ES) that were extensive in three. The buccal mucosa was papillomatous, and the fingernails of all patients were pathological. Two patients experienced intermittent dysphagia. The borders of the ES were finely indented, with a postage stamp appearance. The longitudinal fasciculation of the ES was irregular, interrupted in places, and crenated. In one patient the mucosa appeared rigid and deformed, with large folds. Fibroscopic study of the mucosae confirmed the radiographic findings. They were lined with kerotic pustules that were adherent and situated on mucosae that had lost their flexibility and normal red color. Biopsies showed no pustulous filaments or viral cytopathogenic effects. In two patients intraepidermic fissures were seen in the layers of the Malpighian bodies. Some rare cells found in the integument attested to dyskeratosis.

4391 INTRACTABLE DIARRHEA: INTESTINAL PERFUSION STUDIES AND PLASMA VIP CONCENTRATIONS IN PATIENTS WITH PANCREATIC CHOLERA SYNDROME AND SURREPTITIOUS INGESTION OF LAXATIVES AND DIURETICS. (Eng.) Krejs, G. J.; Walsh, J. H.; Morawski, S. G.; Fordtran, J. S. (Univ. Texas Health Science Center at Dallas, Southwestern Medical Sch., Dallas, TX 75235). *Am. J. Dig. Dis.* 22(4):280-292; 1977.

The secretion and absorption of water and electrolytes were measured using a triple-lumen, small intestinal perfusion method in the jejunum and ileum of 11 patients with a presumptive diagnosis of pancreatic cholera syndrome (PCS). Ultimately, PCS was actually present in only three patients, whereas six were discovered to be taking either laxatives or diuretics surreptitiously. The cause of the diarrhea could not be determined in the two remaining patients. In PCS, the major abnormality was that the jejunal mucosa secreted rather than absorbed when perfused with a plasma-like solution. By contrast, the ileum of the PCS patients absorbed a plasma-like solution normally; however, one patient failed to absorb sodium and chloride when a solution with a low (50 mM) NaCl concentration was perfused in the ileum. The volume of endogenous fluid was high in both the jejunum and ileum, presumably because of proximal small intestinal secretion. Glucose stimulated sodium absorption in all patients. Studies were repeated in one PCS patient after tumor removal, and his intestinal absorption of water and electrolytes was normal. Patients with diarrhea due to surreptitious ingestion of laxatives and diuretics showed normal absorption in the jejunum and ileum. Proximal small-bowel secretion was the major cause for diarrhea in the three patients with PCS. This cannot be a consequence of diarrhea *per se*, since it was not found in patients with long-standing diarrhea due to surreptitious drug ingestion. Small intestine perfusion studies may be helpful in the diagnosis and management of selected cases of severe chronic diarrhea.

4392 TRANSMISSION OF ROTAVIRUS GASTROENTERITIS FROM CHILDREN TO A MONKEY. (Eng.) Mitchell, J. D.; Lambeth, L. A.; Sosula, L.; Murphy, A.; Albrey, M. (Prince of Wales Children's Hosp., Sydney, Australia). *Gut* 18(2):156-160; 1977.

A pooled suspension of rotavirus, prepared from the stools of eight children with acute non-bacterial gastroenteritis, was infused into the duodenum and stomach of an infant monkey *(Nemestrina macaque)* to determine if the virus exhibits species specificity. Biopsy samples of duodenal mucosa were taken at several intervals after inoculation, examined by light and electron microscopy, and assayed for lysosomal activity. Virus-like particles were seen within and around microvilli and intracellularly within vesicles as early as 20 min after the infusion. On the fourth and fifth days, large lysosomal bodies containing numerous virus-like particles were found within epithelial cells of the duodenal villi. No such particles were seen in the pre-inoculation sample or at days 16 or 25 after infection. This is the first demonstration of the transmission of this human virus to another species.

4393 PARACOCCIDIOIDOMYCOSIS OF THE SMALL INTESTINE. ROENTGENOGRAPHIC AND ANATOMOCLINICAL ASPECTS OF 125 CASES. (Por.) Fonseca, L. C.; Mignone, C. (Clin. Med., Fac. Ciencias Medicas de Santos, Univ. Sao Paulo, Sao Paulo, Brazil). *Rev. Hosp. Clin. Fac. Med. Sao Paulo* 31(3):199-207; 1976.

Roentgenographic examination of the small intestine of 125 patients with diagnosed South American blastomycosis revealed a correlation between symptoms of enteritis and small intestine abnormalities. Of 38 patients without intestinal symptoms, 33 had normal roentgenograms, 3 showed increased intestinal motility, and 2 showed abnormalities of intestinal mucosa. Of 87 who reported symptoms (abdominal pain and diarrhea), 31 had normal roentgenograms, and 56 showed abnormalities; 52% showed decreased intestinal motility, and 71.3% had morphological changes, such as thickening, ulcerated or nodular mucosa, jejunocolonic fistula, spasmodic contractions, or hypotonia. Median serum protein levels were lower in the symptomatic group (6.5 g% compared to 8.0 g% in the asymptomatic group). Autopsy in 25 cases revealed 1 case of paracoccidioidomycosis (PCM) of the duodenum, 5 cases of small intestinal PCM, 6 cases of large intestinal plus colon PCM, 7 cases of colon PCM, 5 cases with normal intestines or nonspecific abnormalities, and 20 cases with specific lesions due to *Paracoccidioides brasiliensis*. Twelve case histories are given in detail.

4394 CURRENT BIOLOGICAL ASPECTS OF TYPHOID FEVER. (Fre.) Modai, J.; Coquin, Y. (Hopital Claude-Bernard, 10 av. de la Porte d'Aubervilliers, F 75019 Paris, France). *Nouv. Presse Med.* 6(25):2222-2226; 1977.

The biological criteria, blood and stool cultures and serology, of typhoid fever were studied in 90 patients over a 5-yr period. The patients were treated with chloramphenicol or thiamphenicol (43 patients), ampicillin or trimethoprim-sulfamethoxazole (25), or switched from the first regimen to the second (20) because of the development of neutropenia or complications. Therapy with phenicols was stopped in 20 of the patients. The bacteria was isolated in 79% of blood and 23% of stool cultures, and antibodies (O and H agglutinins) were found in 86% of blood samples. Hemograms taken before and after therapy showed granulocytopenia in patients treated with phenicols as well as those given ampicillin and trimethoprimsulfamethoxazole. The average pretherapy neutrophil count of 4,340-

5,400 mm^3 dropped to 2,860-3,000 mm^3 after treatment. The responsible organism was isolated in 88% of the patients: *Salmonella typhi* (70), *S. paratyphoid* A (2), and *S. paratyphoid* B (7). Typhoid was diagnosed by all three criteria in only 15/90 of the patients, emphasizing the importance of a combination of biological criteria for the diagnosis of typhoid, as more relatively asymptomatic forms begin to appear in the population.

4395 COMPARATIVE STUDY OF THE VALUE OF THE CALCIUM, SECRETIN, AND MEAL STIMULATED INCREASE IN SERUM GASTRIN TO THE DIAGNOSIS OF THE ZOLLINGER-ELLISON SYNDROME. (Eng.) Lamers, C. B. H.; Van Tongeren, J. H. M. (Univ. Hosp. St. Radboud, Nijmegen, Netherlands). *Gut* 18(2):128-134; 1977.

To evaluate the usefulness of provocation tests in the diagnosis of the Zollinger-Ellison (ZE) syndrome, stimulation tests with calcium (15 mg/kg/3 hr) and secretin GIH (1 U/kg/30 sec) were performed in 15 patients with histologically proven or suspected ZE syndrome. In the nine patients without previous gastric surgery, meal-stimulated serum gastrin levels were also measured. These tests were also performed in normal subjects and in patients with duodenal ulcer, antrectomy, total gastrectomy, and achlorhydria. All tests were considered to be positive if a more than a 50% increase in serum gastrin was found. There were only two false-negative test results in ZE patients. There were no false-positive tests in 69 patients without gastrinoma. No complications were encountered. The two ZE patients with negative secretin stimulation tests had negative calcium provocation tests as well, in spite of histologically proven gastrinoma. In 11 patients with suspected or proven ZE syndrome and basal serum gastrin levels of less than 1,000 pg/ml, a rather good correlation ($r=0.841$; $p<0.01$) was found between the percentage increase in serum gastrin after stimulation by calcium and secretin. The results indicate that secretin stimulation is the provocation test of choice in the diagnosis of the ZE syndrome. Meal-stimulated serum gastrin levels are helpful only in patients without previous gastric surgery.

4396 BASAL AND CALCIUM-STIMULATED GASTROESOPHAGEAL SPHINCTER PRESSURE IN PATIENTS WITH ZOLLINGER-ELLISON SYNDROME. (Eng.) Snyder, N.; Hughes, W. (Univ. Texas Medical Branch, Galveston, TX 77550). *Gastroenterology* 72(6):1240-1243; 1977.

To determine the relation between fasting serum gastrin and lower esophageal sphincter (LES) pressure, LES pressure was measured in six patients with the Zollinger-Ellison syndrome (ZES) and hypergastrinemia, and in six patients with duodenal ulcer and normogastrinemia. Basal LES pressure in ZES patients (17.0 ± 3.7 mm Hg) was similar to basal LES pressure in duodenal ulcer patients (18.3 ± 3.5 mm Hg, $p>0.10$). LES pressure and serum gastrin concentration were not related in the ZES patients ($r=0.03$) or in the duodenal ulcer patients ($r=0.20$). Intravenous infusion of calcium gluconate in ZES patients produced a marked rise in serum gastrin concentration ($\Delta=1,580 \pm 1,110$ pg/ml, $p<0.001$), and a moderate but significant rise in LES pressure ($\Delta=5.9 \pm 0.9$ mm Hg, $p<0.05$). In duodenal ulcer patients, calcium infusion produced only slight rises in gastrin concentration ($\Delta=10 \pm 12$ pg/ml), and LES pressure ($\Delta=2.1 \pm 0.5$ mm Hg), which were not significant ($p>0.10$). This study suggests that basal LES pressure is not regulated by blood gastrin levels in the ZES. The calcium infusion study suggests that the LES pressure in patients with ZES may respond to acute changes in endogenous gastrin levels.

Parasitology

4456 ULTRASOUND AND ABDOMINAL HYDATID DISEASE. (Eng.) Vicary, F. R.; Cusick, G.; Shirley, I. M.; Blackwell, R. J. (Univ. Coll. Hosp., Gower St., London WC1, England). *Trans. R. Soc. Trop. Med. Hyg.* 71(1):29-31; 1977.

The cases of seven patients are presented in whom a total of 22 hydatid cysts were located by ultrasound grey-scale and conventional B-scanning techniques. The patients included three women and four men. Nine of the cysts occurred in the peritoneal cavity, and the remainder occurred in the liver. Two patients had previously had hydatid cysts of the lung. Laparotomy confirmed the presenc of 19 abdominal cysts. The grey-scale techniques did not appear to add appreciably to the ease of diagnosis. Ultrasound is useful in the diagnosis of hydatid cysts and in determining their location, volume, and number.

4457 EPIDEMIOLOGIC INVESTIGATION OF ECHINOCOCCOSIS IN AMERICAN INDIANS LIVING IN ARIZONA AND NEW MEXICO. (Eng.) Schantz, P. M.; Von Reyn, C. F.; Welty, T.; Andersen, F. L.; Schultz, M. G.; Kagan, I. G. (Center for Disease Control, U.S. Dept. Health, Education, and Welfare, Atlanta, GA 30333). *Am. J. Trop. Med. Hyg.* 26(1): 121-126; 1977.

As part of a regional epidemiologic study, 10 cases of echinococcosis diagnosed in American Indians in Arizona and New Mexico between 1972 and 1975 were investigated. When possible, patients were visited in their homes to identify factors associated with local parasite transmission, to detect possible additional cases among family members, and to perform diagnostic tests on dogs. Six patients were Navajo, two Zuni, and two Santo Domingo Indians. Since dogs are usually kept in close proximity to the homes, the opportunities for exposure to *Echinococcus granulosus* are numerous. Dogs owned by three of the Navajo patients were infected with *E. granulosus*. Data from epidemiological studies suggest that humans acquired their infections from dogs that had contracted infections from two sources. The first source was sheep raised locally in rural areas of the Navajo reservation where the infection is enzootic in the dog-sheep cycle. The widespread practice of home butchering facilitated the transmission of infection. The second source of human infection was dogs that became infected by eating viscera of sheep of off-reservation origin, which were purchased and butchered by families in urban areas of the Navajo reservation and in the Zuni and Santo Domingo pueblos.

4458 TRANSMAMMARY PASSAGE OF Strongyloides SP. LARVAE IN THE HUMAN HOST. (Eng.) Brown, R. C.; Girardeau, M. H. F. (Medical Benevolence Foundation, Woodville, TX 75979). *Am. J. Trop. Med. Hyg.* 26(2):215-219; 1977.

The prevalence of infection with *Strongyloides fuelleborni* and hookworms (*Ancylostoma duodenale* and *Necator americanus*), and the possible transmammary passage of these parasites, was studied in the residents of an African village. Stool examinations revealed that 34% of 76 infants under 200 days of age were infected with *S. fuelleborni* and 8% were infected with hookworms. Infection rates in the general population were 44% for *S. fuelleborni* and 90% for hookworms. The examination of 113 milk samples from 25 nursing mothers revealed the presence of *Strongyloides* larvae in one case; stool specimens of her child were negative for eggs and parasites at 5 days of age. *S. fuelleborni* may be transmitted via the milk in humans but further studies are necessary to clarify the matter.

4459 EOSINOPHILIC GRANULOMATOUS HEPATITIS. REPORT OF A CASE OF TOXOCARIASIS. (Fre.) Bogomoletz, W. (Queen Mary's Hosp., Rochampton, London SW 15, England). *Ann. Anat. Pathol. (Paris)* 22(1):75-79; 1977.

A case of eosinophilic granulomatous hepatitis, due to toxocariasis, in a 2-yr-old girl and the problem of histological differential diagnosis is presented. The girl had anorexia and asthenia for 2 months. Marked hepatomegaly, moderate ascites, and an enlarged heart were found on examination. Bone marrow and ascitic fluid contained numerous eosinophils. Progressive and marked eosinophilia with a constant rise in IgE and a hemoglobin of 7 g were present. Liver biopsy revealed a single histiocytic and giant cell granuloma without necrosis but with numerous eosinophils. Serial sections showed no parasites or microorganisms in the lesion, and a differential diagnosis of a hypereosinophil syndrome with polyvisceral lesions was made. Seroimmunological reactions were positive for *Toxocara canis*. The family had two dogs, both bearers of *T. canis*, and two members of the family had highly elevated eosinophilia and IgE as well as positive tests for *T. canis*. The patient was treated with prednisolone and thiabendazole. Hepatomegaly and cardiomegaly diminished and ascites disappeared but eosinophilia (3,000-5,000 eosinophils/mm^3) persisted.

GENERAL

Regional Enteritis

4465 TREATMENT OF CROHN'S DISEASE WITH HOME PARENTERAL NUTRITION. (Eng.) Rault, R. M. J.; Scribner, B. H. (Dept. Medicine, Univ. Washington, Seattle, WA). *Gastroenterology* 72(6): 1249-1252; 1977.

Nine cases of severe Crohn's enterocolitis in patients treated by home parenteral nutrition are described. Seven patients had a short bowel syndrome after multiple bowel resections. In two patients home parenteral nutrition was used as primary therapy. The treatment was well tolerated and proved successful in eight patients. Three patients have been able to discontinue parenteral infusions and currently are in remission. The main complications were associated with the access device, which was replaced in three patients. Five patients currently have abnormal liver function tests without progressive liver disease. In two patients with active inflammatory bowel disease complicated by perirectal or intraabdominal sepsis, marked improvement occurred while on home parenteral nutrition. It is concluded that home parenteral nutrition is an important new therapeutic modality that can reduce or even eliminate the need for repeated or prolonged hospitalization of patients with short bowel syndrome complicating severe Crohn's disease. Home parenteral nutrition, because it is relatively simple and safe, lends itself to early intervention in severe fulminant cases of Crohn's disease. The patient is more rapidly rehabilitated, and his fear of early relapse and recurrent malnutrition is minimized, thus facilitating a prolonged period of bowel rest that can lead to eventual remission. Home parenteral nutrition should be kept in mind as a possible alternative to early surgical intervention in selected cases of severe Crohn's disease.

4466 GROWTH, COURSE, AND PROGNOSIS AFTER SURGERY FOR CROHN'S DISEASE IN CHILDREN AND ADOLESCENTS. (Eng.) Homer, D. R.; Grand, R. J.; Colodny, A. H. (Children's Hosp. Medical Center, 300 Longwood Ave., Boston, MA 02115). *Pediatrics* 59(5):717-725; 1977.

Thirty-seven children and adolescents were followed from 2 to 26 yr after resections for Crohn's disease in order to determine the long-term responses to such surgery. Twenty-eight patients had disease that involved both the colon and terminal ileum; disease was limited to the small intestine in eight patients and to the stomach in one. At the time of surgery 16 patients were at or below the third percentile for weight and only 16 had reached puberty (all of these were older than 14.5 yr). Fourteen patients (11 prepubertal, 3 pubertal) had severe impairment of linear growth; height was at or below the third percentile or linear growth was absent for more than a year. At the time of the first operation, seven patients had incomplete resections and have had persistent disease. The remaining 30 patients had complete resections as determined by gross and histological criteria. Of these, 12 have had recurrences and 18 have been free of disease. Of the 11 prepubertal patients with preoperative linear growth failure, only 2 had catch-up growth after surgery. The remaining nine and all of the pubertal patients have either failed to grow or have maintained their height in their preoperative percentile. Catch-up growth after surgery for Crohn's disease occurs only in children operated on before puberty in whom there is no early recurrence. The recurrence rate for this group of patients was 30%; most recurrences occurred within 2 yr of the initial resection. Growth failure may be considered to be an important indication for surgery in the prepubertal child with Crohn's disease, but it probably is not an indication after onset of puberty.

4467 BILE ACID METABOLISM AND PLASMA PROTEIN TURNOVER IN CROHN'S DISEASE. (Eng.) Lenz, K.; Jensen, K. B.; Jarnum, S. (Rigshospitalet, Copenhagen, Denmark). *Gastroenterology* 11(7):721-727; 1976.

Postprandial duodenal bile acids, intestinal protein loss, and albumin and IgG turnover were studied in 19 patients with Crohn's disease and in 20 patients with chronic diarrhea to establish an interdependence between these parameters in Crohn's disease. Duodenal bile acid concentration was decreased in 9 of 19 patients with Crohn's disease and in 5 of 20 patients with unexplained diarrhea. Free bile acids were found in the duodenal juice of one patient only. The glycine/taurine ratio increased in 8 of 17 patients with Crohn's disease, but in only one of the 20 control patients. Abnormal intestinal protein loss was present in 13 of 14 patients with Crohn's disease. The fractional catabolic rate of albumin and of IgG increased in all 17 cases of Crohn's disease studied except the patient with free bile acids and no abnormal protein loss. The glycine/taurine ratio was significantly correlated to the fractional catabolic rate of albumin ($r=0.54$, $p<0.05$) and to that of IgG ($r=0.70$, $p<0.01$), which are always present in active Crohn's disease. It is concluded that the glycine/taurine ratio is a valuable indicator of terminal ileopathy in nonoperated patients with terminal ileitis.

4468 ANALYSIS OF THE LYMPHO-PLASMACYTIC INFILTRATE IN CROHN'S DISEASE WITH SPECIAL REFERENCE TO IDENTIFICATION OF LYMPHOCYTE-SUBPOPULATIONS.

(Eng.) Meuwissen, S. G.; Feltkamp-Vroom, T. M.; De La Riviere, A. B.; Von Dem Borne, A. E.; Tytgat, G. N. (Central Lab. Netherlands Red Cross Blood Transfusion Service, Amsterdam, Netherlands). *Gut* 17(10):745-836; 1976.

Lympho-plasmocytic infiltrates in cryostat sections from patients with Crohn's disease (29), ulcerative colitis (16), and control subjects without inflammatory diseases (12) were studied. Specific antilymphocyte antiserum and a specific anti-T-lymphocyte antiserum were used. T-cells were present in inflammatory infiltrates, particularly in the deeper layers of the bowel wall, while non-T-lymphocytes predominate (± 70-80%) in the more superficial layers of the gut, in lymphoid follicles, and around areas of ulceration. Increased numbers of T-cells were found infiltrating between muscle fiber. Epitheloid cell granulomata was detected in the submucosa. Immunoglobulins containing plasma cells were counted, using specific IgA, IgM, and IgG antisera in serial sections. Reduction in the number of IgA-containing plasma cells in the lamina propria, particularly in areas with the characteristic transmural inflammation of Crohn's disease patients was reported. This resulted in a significant reduction of the IgA/IgM plasma cell ratio in Crohn's disease, in comparison with ulcerative colitis and controls. Further analysis of the morphology and function of T-lymphocytes and T-lymphocyte subpopulations is suggested.

4469 THE EXTRA-INTESTINAL COMPLICATIONS OF CROHN'S DISEASE AND ULCERATIVE COLITIS: A STUDY OF 700 PATIENTS.

(Eng.) Greenstein, A. J.; Janowitz, H. D.; Sachar, D. B. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY). *Medicine* 55(5):401-412; 1976.

Extra-intestinal complications in four groups of patients with regional enteritis (213 patients), ileocolitis (223), Crohn's colitis (62), and ulcerative colitis (202) were reported. Incidence of colitis-related manifestations (joint, skin, mouth, and eye disease) was higher in patients with Crohn's disease ($p<0.001$, 42%) than in patients with disease restricted exclusively to the small bowel (23%). These complications occurred in 36% of patients and responded to medical or surgical treatment of the underlying bowel disease; joints were involved in 23% of the cases, skin in 15%, and the mouth and eyes in 4% each. Erythema nodosum was significantly more frequent in Crohn's disease ($p<0.05$), and pyoderma gangrenosum was observed most often in ulcerative colitis ($p<0.05$). Disorders related to small bowel pathophysiology included malabsorption, gallstones, kidney stones, noncalculous hydronephrosis, and hydroureter. Malabsorption was associated with ileocolitis and regional enteritis (6.7%), while gallstones (11%) and renal stones (9%) were more frequent in Crohn's disease. Osteoporosis or osteomalacia was reported in ulcerative colitis (3%), granulomatous colitis (5%), and disease of the small bowel (3%). Generalized demineralization was reported in two patients. Liver disease (5%), peptic ulcer (10%), and amyloidosis (1%) were reported in some patients.

4470 RADIOLOGICAL FINDINGS IN ESOPHAGITIS DUE TO CROHN'S DISEASE.

(Ger.) Frohlich, H.; Huchzermeyer, H.; Stender, H. St. (Institut fur klinische Radiologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, 3000 Hannover-Kleefeld, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 125(6):497-300; 1976.

The radiological changes in esophagitis due to Crohn's disease (CD) are described in five patients. Heterogeneous radiological, anatomical, and histological findings were noted. Increasing mucosal relief of the middle and lower esophagus was seen in a 12-yr-old boy who did not develop stenosis. Histologically, there were only widespread ulcerous and nonspecific inflammatory changes. However, the patient died from severe toxic shock after colonic perforation. Autopsy confirmed CD with involvement of the mouth, esophagus, ileum, and colon. Another patient showed rigid stenosis in the lower third of the esophagus. Esophagectomy revealed multiple ulcers and nonspecific granulocyte inflammation of the entire esophageal wall, with involvement of the lymph nodes and widespread submucosal fibroses. The patient died postoperatively of circulatory failure. The third patient developed a conical constriction of the lumen after a Billroth II operation. Stenosis with prestenotic esophageal dilatation and a hyperemic edematous mucosa with white fibrin deposits were seen by esophagoscopy. Histologically, highly ulcerated epithelia with marked inflamed WBC infiltration as well as capillary-rich granulation tissue were noted. The patient died 3 weeks postsurgery; autopsy confirmed CD. Similar findings were found in the fourth patient. Persistent constrictions were noted in the fifth patient, who presented with dysphagia, pain, and pressure behind the sternum. Irregular stenosis of the esophagus, which was suspected to be a stenosing carcinoma of the esophagus, developed within 4 months. At esophagectomy, the overgrown esophagus was severed and anastomized to the fundus. Histologically, regional enteritis of the esophagus was confirmed. At a 5-yr follow-up, no abnormalities were noted.

4471 CROHN'S DISEASE OF THE ESOPHAGUS. (Fre.) Gaucher, P.; Bigard, M. A.; Begue, J. Y.; Laugros, A.; Regent, D.; Macinot, C. (C.H.U. de Nancy-Brabois, F 54500 Vandoeuvre, France). *Nouv. Presse Med.* 6(16):1369-1372; 1977.

Esophageal localization was demonstrated in 3/18 patients with Crohn's disease (11 women, 7 men; mean age of 31 yr) by routine endoscopy of the esophagus with multiple biopsies. Clinical symptoms were absent in the other 15 patients, whereas the 3 patients with esophageal lesions had epigastric heartburn. Radiology detected ulceration in two patients but no stenosis. Endoscopy showed esophagitis in three patients; two of three patients had previously presented with multiple esophageal lesions. Histological examination of the biopsies revealed inflammation in five, and a case of nonspecific transmural inflammatory infiltration. An epithelioid granuloma was discovered in two of three patients with esophageal localization, which have not previously been reported in the literature. In conclusion, esophageal localizations underline the ubiquitous character of Crohn's disease and emphasize the importance of endoscopy.

4472 INVOLVEMENT OF THE STOMACH IN CROHN'S DISEASE. (Ger.) Hirt, J. J.; Junginger, T.; Frotz, H.; Tismer, R. (Chirurgische Universitatsklinik, Joseph-Stelzmann-Strasse 9, D-5000 Koln 41, W. Germany). *Leber Magen Darm* 6(3):168-171; 1976.

Involvement of the stomach, ileum, and colon was observed in a 31-yr-old man operated on for Crohn's disease (CD). Only in 2% of cases of CD is the stomach involved, and this man was 1 of a series of 59 CD patients. Initially, the patient experienced diarrhea, nausea, vomiting, and abdominal pain. X-ray examination of the stomach revealed marked initial stenosis with filling defect, and a subsequent examination of the antrum showed widespread stenosis of the prepylorus. Gastroscopy revealed erosive, aphthoid lesions; biopsy confirmed the diagnosis of CD of the stomach. Contrast radiography showed stenosis of the transverse colon and inflammatory changes in the cecum with typical signs of granulomatous colitis. Coloscopy detected inflammation of the mucosa, ulceration, and stricture of the lumen. Laparotomy showed that the duodenum was free of inflammatory changes. A distal hemigastrectomy was performed; the terminal ileum and ascending and transverse colon were excised. Histological examination of the excised tissue showed signs of CD. No postoperative complications developed and the patient returned to work.

4473 MANIFESTATIONS OF REGIONAL ENTERITIS (CROHN'S DISEASE) IN THE STOMACH AND DUODENUM. (Ger.) Koischwitz, D.; Brecht, G.; Gerlach, F.; Lackner, K. (Radiologische Klinik der Universitat Bonn, 5300 Bonn-Venusberg, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 125(6):501-507; 1976.

The manifestations of Crohn's disease in the stomach and duodenum of nine patients are presented. Tissue specimens were taken in all patients by endoscopy. Only one patient had histological mucosal changes typical of the disease, whereas the others showed uncharacteristic mucosal inflammation. The most common symptoms were stomach pain, mainly in the right lower stomach and epigastrium, diarrhea, nausea, and vomiting. Typical radiological changes were seen in the stomach and duodenum of all patients. Cobblestone mucosa of the antrum and pars pylorica was evident in four patients. Six patients also had multiple needle-sized ulcers of the antrum, whereas three had a funnel-shaped narrowing of the antrum. The changes extended to the duodenal bulbus and descending colon in eight patients. Duodenal stenosis was also evident in three patients, and one had a deformity of the pylorus. One patient died of renal insufficiency with amyloidosis. Gastroenterostomy with selective vagotomy was done in one patient with gastric stenosis. One patient, who previously had a gastroenterostomy, developed stenosis in the area of the duodenojejunal flexure. Following a duodenojejunostomy, the patient remained symptom-free. One patient had an ileocolectomy and one, a hemicolectomy, whereas four were treated with conservative drug therapy.

4474 ANAL AND PERIANAL COMPLICATIONS OF CROHN'S DISEASE. (Ger.) Krieg, H.; Brunner, H.; Gamstatter, G.; Gronninger, J. (Chirurgische Klinik der Universitat, Langenbeckstrasse 1, D-6500 Mainz, W. Germany). *Munch. Med. Wochenschr.* 119(6):193-196; 1977.

Anal complications associated with Crohn's disease (CD) were noted in 59/153 patients. Widespread fistulas of the anal or perianal region were conspicuous. Crohn's disease-like skin and mucosal changes in the form of granulomatous infiltrates and fissures were observed less frequently. A diagnosis of severe proctitis with mucosal ulceration and scarred stenosis was made in 11 patients. The foci of the intestinal disease in the 59 patients were mostly in the terminal ileum. Crohn's disease restricted to the rectum was observed in four patients. An enterectomy was performed in 49 patients with inflamed primary foci, followed by end-to-end anastomosis; the surgery included nine coloproctectomies and six abdominosacral proctectomies. A preterminal natural anus was created in 11 patients until local inflammation had healed. Postoperative anal complications developed in 30% of the patients. Some had renewed lesions indicative of recurrences or exacerbation of a nonaffected area. Fistulization at the anal wound cavity was seen in one patient. One patient had a markedly slower formation of granular tissue after drainage of the abscesses and fistulas and a delay in wound healing in the sacral area after rectal extirpation. Intestinal resection is the suggested therapy for Crohn's disease with anal complications. Local surgical measures may endanger continence and is appropriate only in certain cases.

4475 OXALATE RENAL STONES AND GALLSTONES AFTER ILEAL RESECTION FOR CROHN'S DISEASE. (Fre.)

Capron, J. P.; Dupas, J. L.; Delamarre, J.; Joly, J. P.; Abourachid, H.; Lorriaux, A. (Centre Hospitalier Universitaire, 1, place Victor-Pauchet, F 80030 Amiens, Cedex, France). *Gastroenterol. Clin. Biol.* 1(2):165-169; 1977.

Oxalate renal stones and gallstones developed in a 64-yr-old man with Crohn's disease 15 yr after extensive (110 cm) ileal resection. Upon discovery of Crohn's disease, the patient was given a right hemicolectomy and a 30-cm resection of the ileum subsequent to an occlusive syndrome. He was well for 5 yr when symptoms of blocked intestinal transit recurred at which time he was subjected to an ileal resection (80 cm). Fifteen years later, the patient complained of right renal colic and hematuria. Radiography revealed large pyelocaliceal and gallbladder calculi, and surgical removal of the right renal calculi showed them to be composed of calcium oxalate. The patient had oxaluria, 60 mg/day, (normal, <25 mg) and fecal fat excretion was 50 g/day (normal, <6 g). Following 3 months of a low-oxalate and low-fat diet, steatorrhea was reduced to 6 g/day, but oxaluria was still elevated (80 mg/day). The effectiveness of such a diet in this disorder has not been demonstrated.

4476 RHEUMATIC MANIFESTATIONS OF CROHN'S DISEASE. A DISCUSSION OF THE RESULTS OF A NATIONAL SURVEY. (Fre.)

Deshayes, P.; Houdent, C.; Hecketsweiler, Ph. (Centre Hospitalier Universitaire, Hotel-Dieu, F 76038, Rouen CEDEX, France). *Rev. Rhum.* 43(10):541-551; 1976.

The results of a national survey of rheumatic manifestations of Crohn's disease (CD) in 102 patients are presented and the literature is reviewed. These rheumatic manifestations were classified as peripheral (47) or skeletal (55). In the 47 patients with peripheral rheumatism (28 women and 19 men), the diagnosis of CD was made anatomically in 21 and by radiological criteria only in 26. Clinically, these patients had arthralgias (15), regressive arthritis (25), and polyarthritis (7). Enteritis was closely associated with articular flare-ups. Other associated symptoms included erythema (14), conjunctivitis (4), and iritis (1). Tests for rheumatoid factor were always negative, but synovial fluid showed signs of inflammation in eight patients. Treatment with salicylates and anti-inflammatory agents benefitted 5/10 patients, and the effectiveness of corticoids was notable in 11 patients. Salapyrine had little effect on rheumatic symptoms. Of the 55 patients with skeletal manifestations, 32 had ankylosing spondylitis (equally distributed between the sexes). One-half of the cases of spondylitis were associated with ileocolitis; 21 patients (12 men and 9 women) presented with mono-, oligo-, or polyarticular evolution of arthralgia or arteritis. Less peripheral involvement was noted in forms with syndesmosis than in forms without. Extra-articular localizations were rarely seen and the evolution of spondylitis did not seem related to enteritis. A study of the histocompatibility antigen (HL-A) system revealed a positive test for the B 27 antigen in only one woman. In CD, ankylosing spondylitis and sacro-ileitis seem to be controlled by a genetic factor different from the HL-AB 27 marker.

4477 INDUCTION OF GRANULOMAS IN MICE BY INOCULATION OF TISSUE HOMOGENATES FROM PATIENTS WITH INFLAMMATORY BOWEL DISEASE AND SARCOIDOSIS.

(Eng.) Taub, R. N.; Sachar, D.; Janowitz, H.; Siltzbach, L. E. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Ann. N.Y. Acad. Sci.* 278:560-564; 1976.

Studies were carried out to determine if granuloma could be induced in CBA mice by the injection of homogenates of affected intestinal tissue from patients with inflammatory bowel disease and of homogenates of spleen from sarcoidosis patients. Mice inoculated with bowel homogenates from 13 patients with Crohn's disease and from 4 with ulcerative colitis developed epithelioid granulomas at the injection site. The granulomas were most numerous and florid in mice injected with actively inflamed granulomatous material. However, granulomas were also seen in mice inoculated with homogenates of tissue taken from the normal resection margin of the ileal or colonic specimen in six of nine patients. Homogenates taken from control patients undergoing resection for unrelated diseases produced granulomas in four of nine instances. The results indicate that material with potent granuloma-eliciting activity is present in the lymph nodes in some patients, and in affected intestinal tissues of all patients with ulcerative or granulomatous inflammatory bowel disease.

4478 CASE REPORT: AN UNUSUAL CASE OF CROHN'S DISEASE IN A WEST INDIAN CHILD. (Eng.)

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism an Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

4483 LANGERHANS CELLS IN THE HUMAN OESOPHAGUS. (Eng.) Yassin, T. M. A.; Toner, P. G. (Glasgow Royal Infirmary, Glasgow, Scotland). *J. Anat.* 122(2):435-445; 1976.

The dendritic cells of Langerhans were observed by electron microscopy in the middle and superficial layers of 10 specimens of normal human esophageal mucosa. These cells did not occur in the basal layer or beneath the basal lamina. They exhibited typical Langerhans granules, but no desmosomes or tonofilaments. They were often irregular in outline with cytoplasmic protrusions that extended out from the perikaryon between the surrounding squamous cells. The cells usually had irregular indented nuclei, with a relatively pale cytoplasm contrasting with that of the adjacent squamous cells. The Langerhans cells were sometimes difficult to distinguish from intra-epithelial lymphocytes. Like Langerhans cells, these lymphocytes lacked tonofilaments and desmosomes, but they differed from typical Langerhans cells in that they did not have characteristic granules, their cytoplasmic organelles were less well organized, and their nuclear morphology had a more prominent heterochromatin component.

4484 HISTOCHEMICAL STUDIES OF MUCOSUBSTANCES AND LIPIDS IN NORMAL HUMAN OESOPHAGEAL EPITHELIUM. (Eng.) Hopwood, D.; Logan, K. R.; Coghill, G.; Bouchier, I. A. D. (Ninewells Hosp. and Medical Sch., Dundee, Scotland). *Histochem. J.* 9(2):153-161; 1977.

The carbohydrate mucosubstance and lipid histochemistry of normal human esophageal epithelium were investigated to establish a baseline for studying the diseased esophagus. Esophageal biopsies were obtained from 24 patients undergoing upper gastrointestinal endoscopy. The following previously identified layers were seen in the esophagus: the basal layer (a single layer of columnar cells), the prickle cell layer (several layers of polygonally shaped cells with numerous intercellular bridges), and the functional layer (several layers of cells, increasingly flattened towards the lumen). Neutral fat droplets, 1-2 μm in diameter, were present in all layers, the greatest number being in the functional layer cells. No unsaturated lipids or fatty acids were demonstrable. PAS and diastase digestion techniques revealed a large amount of glycogen in the cytoplasm of the prickle and functional cell layers. The intercellular space of the most superficial of the functional cell layer contained neutral and sialic acid-rich acid mucopolysaccharides. The authors suggest that these may be important in protecting the epithelium against physical and chemical trauma.

4485 ELECTRON HISTOCHEMISTRY OF MUCOSUBSTANCES IN NORMAL HUMAN RECTAL EPITHELIUM. (Eng.) Coghill, S. B.; Hopwood, D. (Ninewells Hosp. and Medical Sch., Dundee, Scotland). *Histochem. J.* 9(2):231-240; 1977.

The electron histochemistry of mucosubstances was studied in the normal rectal epithelium of 11 subjects to establish the pattern of reactivity of this tissue with the various tests available. The fuzzy coat, glycogen, lysosomes, Golgi apparatus, and theca were regularly stained with the periodic acid-chromic acid-methenamine silver technique. There was a gradient of increasing intensity of staining between the forming and maturing faces of the Golgi apparatus. The individual mucin packages that comprise the theca were not stained evenly, and often three discrete densities of staining were identified. Periodic acid oxidation followed by either thiosemicarbazide and osmium tetroxide or silver proteinate demonstrated the theca, lysosomes, and glycogen; the silver proteinate variant also outlined the Golgi apparatus, endoplasmic reticulum, and secretory vesicles in the goblet cells and the secretory granules of enterochromaffin cells. Phosphotungstic acid staining gave a distribution of mucosubstances similar to that revealed by the oxidation techniques. For demonstrating intracellular mucosubstances, the periodic acid-chromic acid-methenamine silver and phosphotungstic acid techniques were the most consistent. Glycogen was demonstrable by the periodate oxidation methods and the complex cyanide technique. Alcian blue, ruthenium red, and concanavalin A stained components on the cell surfaces only. The distribution of acid and neutral mucosubstances on the cell surface and among the various normal epithelial components revealed in this study will serve as a baseline for comparison with diseased tissue.

4486 BRUSH BORDER MOTILITY: MICROVILLAR CONTRACTION IN TRITON-TREATED BRUSH BORDERS ISOLATED FROM INTESTINAL EPITHELIUM. (Eng.) Mooseker, M. S. (Dept. Anatomy, Harvard Medical Sch., Boston, MA 02115). *J. Cell Biol.* 71(2):417-433; 1976.

A model for microvillar contraction in the brush borders of chicken, rat, rabbit, and pig intestinal epithelial cells is proposed based on light and electron microscopy of contractions induced *in vitro*. The addition of calcium and ATP to isolated brush borders pretreated with Triton X-100 resulted in retraction of the microfilament bundles into and through the terminal web. Biochemical analysis showed the main protein of the brush border to be actin, but proteins with properties similar to those of myosin (200,000 daltons), tropomyosin (30,000 daltons), and a z-band protein, α-actin (95,000 daltons), were also detected. A potassium-EDTA ATPase activity of 0.02 μmol phosphate/mg/min (22 C), characteristic of vertebrate myosin ATPase, was found. These results indicate that microvillar contraction is the result of an actomyosin interaction. A model for the interaction of actin and myosin in the microvilli and the relationship of the two substances to the terminal web is compared with another recently proposed model.

4487 CELL LOSS FROM NORMAL AND STRESSED GASTRIC MUCOSAE OF THE RAT. AN ULTRASTRUCTURAL ANALYSIS.

(Eng.) Harding, R. K.; Morris, G. P. (Queen's Univ., Kingston, Ontario, Canada K7L 3N6). *Gastroenterology* 72(5):856-863; 1977.

Scanning and transmission electron microscopy were used to study mechanisms of surface epithelial cell (SEC) loss from the gastric mucosae of normal, fasted Charles River rats and of rats exposed to acute stressors. In fasted control animals, SEC loss occurred primarily via extrusion of individual interfoveolar cells and only rarely by degeneration *in situ*. Each extruding cell was surrounded by a rosette-like configuration of adjacent, encroaching SEC. Mucosal integrity was maintained. Short-term exposure to acute stressors (free operant avoidance training, serosal application of acetic acid, hemorrhagic shock, or mucosal exposure to acidic solutions of acetylsalicylic acid) resulted in an increase in the incidence of extrusive cell loss. Continued exposure to stressors also increased the incidence of degeneration *in situ* of isolated SEC or groups of SEC. Extrusion provides a mechanism for the necessary removal of gastric SEC. Acute stress may override or exhaust the extrusive mode, producing, via ischemia or surface diffusion of cytotoxic agents, SEC degeneration *in situ* and breaks in the mucosal barrier.

4488 MORPHOMETRIC STUDIES OF THE CELLS LINING THE RAT STOMACH IN CHRONIC ALCOHOLISM.

(Ger.) Al-Abadi, H.; Dumke, K.; Donhuijsen, K.; Niedobitek, F. (Stadt. Auguste-Viktoria-Krankenhaus, Pathol. Institut, Rubensstrasse 125, D-1000 Berlin 41, W. Germany). *Z. Gastroenterol.* 15(1): 1-8; 1977.

The effect of 15% alcohol, given *ad libitum* for 8 days, 2, 4, 8, and 12 weeks, on the morphometry of the parietal cells lining the stomach was studied in 84 male Wistar rats. The rats were divided into 12 groups of 5 rats; 24 additional rats served as controls. The parietal cells were stained with congo red for histological sectioning, and with a modified Papanicolaou's stain for cytological examination. The cell and nuclear surface as well as the nucleus-plasma ratio were measured using an integrated smear disc and a microvideomet. Both histological and cytological preparations showed a significant increase (43%) in parietal cell surface during alcohol treatment. The cytoplasmic surface increased continuously up to the 8th week. However, alcohol application for 12 weeks resulted in a decrease (33%) in the cytoplasmic surface. The nuclear surface increased by 10% following an 8-week alcohol treatment, but decreased by 7.5% by the 12th week of treatment. The nucleus-plasma ratio was dependent on the increase in the plasma surface and, therefore, showed a 36% decrease. In all cytological preparations, the microvideomet technique produced larger results for the total cell surface than the integrated smear disc; the size of the nucleus was smaller with the microvideomet technique.

4489 IDENTIFICATION OF GASTRIN-SECRETING CELL AND CHOLECYSTOKININ-SECRETING CELLS IN THE GASTROINTESTINAL TRACT OF THE HUMAN FETUS AND ADULT MAN.

(Eng.) Dubois, P. M.; Paulin, C.; Chayvialle, J. A. (Laboratoire d'Histologie et Embryologie, U.E.R. Medicale, Lyon Sud-Ouest, B.P. no. 12, F-69600 Oullins, France). *Cell Tissue Res* 175(3):351-356; 1976.

Gastrin- and cholecystokinin (CCK)-containing cell were detected using anti-gastrin and anti-CCK sera in the gastrointestinal tracts of 5- to 24-week-ol human fetuses and premature infants, and in the stomach and duodenum of eight adult patients with normal gastroduodenal endoscopy. In adult man and in the 20-week-old fetus, the immunocytological reaction was positive in the antrum only with anti gastrin serum. Both gastrin and CCK were present in the juxtapyloric region. Outside the juxtapylo region, the endocrine cells were stained with the anti-gastrin serum as well as with the anti-CCK serum. No cells were stained with the anti-gastri serum incubated with CCK at a concentration equal to 1 mg/ml of nondiluted serum. Adding gastrin to the anti-CCK serum did not alter the immunocytological reaction due to this serum. It may be considered that the anti-gastrin serum incubated with CCK was rendered completely specific for gastrin. No cross reaction took place between the anti-CCK serum and gastrin. Heterologous antigens (secreti somatostatin, glucagon, insulin, serotonin, and histamine) did not inhibit the immunocytochemical reaction due to each antiserum. Gastrin cells wer first seen in the fetal duodenum as early as 10 weeks of age. Before 14 weeks of age, no gastrin-containing cells were found in the antrum. The fi CCK cells were seen in the small intestine of the 10-week-old fetus. The data demonstrate that gast cells and CCK cells may be identified in the fetus and in adults by a simple technique that can be us in diseases where disorders of CCK or gastrin meta olism are present.

4490 THE PIT CELL: DESCRIPTION OF A NEW TYPE OF CELL OCCURRING IN RAT LIVER SINUSOIDS AND PERIPHERAL BLOOD.

(Eng.) Wisse, E.; van't Noordende, J. M.; van der Meulen, J.; Daems, W. Th (Lab. Electron Microscopy, Univ. Leiden, Rijnsburg erweg 10, Leiden, Netherlands). *Cell. Tissue Res.* 173(4):423-435; 1976.

A new type of cell, called the pit cell, was obser in liver sinusoids and the peripheral blood of mal Wistar rats by electron microscopy. Pit cells con tain highly characteristic granules with electron dense inclusions, are situated in the wall of rat liver sinusoids, and have hyaloplasmic pseudopodia intermingling with the microvilli of the parenchym cells. The characteristic granules are mainly sit uated at one side of the nucleus, with the other side showing organelle-free hyaloplasm. Pit cells are also found in portal tracts and in granuloma-like cellular aggregates. They also occur in the buffy coat of rat peripheral blood but differ from those in liver sinusoids in terms of the number of granules per cell section (6.6 ± 2.5 versus 12.9 ± 4.9, resp.; $p<0.05$), the diameter of the dense inclusions (0.43 ± 0.10 μ versus 0.28 ± 0.05 μ, resp.; $p<0.05$); and the diameter of their mitochondria (0.30 ± 0.04 μ versus 0.41 ± 0.08 μ, resp.; $p<0.05$). Pit cells can be regarded as regular inhabitants of the sinusoidal wall and therefore belong to the series of sinusoidal cells, i.e., the endothelial, Kupffer, and fat-storing cells. Pit cells do not phagocytize and do not react to a number of experimental conditions to which endothelial and Kupffer cells react. No signs of endocytotic activity of pit cells were seen after the i.v. injection of Thorotrast, Latex, Zymosan, or horseradish peroxidase. A single example of pit cell mitosis was found in normal liver. The function of pit cells remains obscure, but an endocrine function is suggested by the morphology of their highly characteristic granules.

4491 THE SURFACE CHARACTERISTICS OF THE PLASMA MEMBRANE OF THE EXOCRINE PANCREAS. (Eng.) Katsuyama, T.; Spicer, S. S. (Dept. Pathology, Shinshu Univ., Matsumoto, Japan). *Am. J. Anat.* 148(4): 535-554; 1977.

To elucidate functional specializations related to fluid and electrolyte transport, regional differentiation of the plasma membrane and related structures of the rat exocrine pancreas were studied ultrastructurally and cytochemically. Fixation with an osmium tetroxide-silver acetate solution produced abundant fine precipitates on the luminal and basal surface of the centroacinar but not the acinar cells. Dialyzed iron (DI) staining revealed the heaviest concentration of anionic sites on the luminal plasma membrane of the acinar cells, including the surface of both the intercellular canaliculi and the main lumen. The reactive sites on the apical acinar plasmalemma appeared to consist of discrete globules. DI-reactivity of the lateral basal membranes was most prominent in the centroacinar cells and essentially absent in the acinar cells but was weak relative to that of the acinar-cell apical plasmalemma. The lamina lucida of the basement membrane of the duct stained with DI, but that of basement membrane under acinar cells did not. Sialidase digestion prior to DI staining abolished the staining of plasma membranes. These results indicate that duct epithelial cells, including most prominently the centroacinar cells, are chiefly responsible for electrolyte and fluid transport.

4492 IONIC COMPONENTS OF SECRETORY CELL SURFACES IN RELATION TO SECRETORY FUNCTION. (Eng.) Katsuyama, T.; Spicer, S. S. (Medical Univ. South Carolina, 80 Barre St., Charleston, SC 29401). *Histochem. J.* 9(4):467-493; 1977.

Rat pancreas was examined by ultrastructural cytochemical methods to localize cations and anions, as well as polyanions and sulfated mucosubstances. Antimonate-precipitable cation was abundant between pancreatic acinar cells and at the base of the centroacinar and other duct epithelial cells. Precipitates of nuclear heterochromatin appeared lighter, whereas those of mitochondria and cytoplasm were more coarse and more conspicuous in acinar than duct cells. Stimulation with synthetic secretin (0.1 U, i.v.) diminished nuclear antimonate reactivity and the precipitation at the basement membrane of centroacinar cells. At a higher dose (1.0), secretin selectively eliminated precipitation between and below centroacinar and other duct cells and increased the amount of antimonate-reactive cation in centroacinar cells and the acinar lumens. Pancreozymin stimulation (1.0 U, i.v.) eliminated antimonate-precipitable cations between acinar cells and, to a much lesser extent, those between duct cells and increased cytoplasmic precipitates on the granular reticulum of acinar cells. Silver-precipitable anions were localized on the luminal surface of the apical plasmalemma and the outer surface of the laterobasal plasmalemma of centroacinar cells but not on acinar cell surfaces. Silver precipitates also occurred on junctional complexes of acinar and duct epithelial cells, at tight junctions of acinar cells, and on the inner face of the lateral plasmalemma of acinar cells. Dialyzed iron staining demonstrated the most number of sites of acid mucosubstance on the luminal surface of the plasmalemma of acinar cells. Lateral and basal plasmalemmas of centroacinar and more distal duct cells stained lightly with dialyzed iron, but those of acinar cells did not. Dialyzed iron visualized acid mucosubstances in the lamina lucida of the basement membrane of duct but not of acinar cells. Dialyzed iron staining of the plasma membranes succumbed to prior sialidase treatment, whereas that of basement membrane resisted digestion. High iron diamine staining demonstrated sulfated mucosubstance in the lamina lucida of the duct basement membrane exclusively. The cytochemical results implicate centroacinar cells as primarily responsible for contributing fluid and electrolytes to pancreatic secretion.

4493 REGULATION OF THE GROWTH OF THE GASTROINTESTINAL MUCOSA [Abstract]. (Eng.) Crean, G. P. (Gastrointestinal Centre, Glasgow, Scotland). *Rend. Gastroenterol.* 9(1):72-73; 1977.

4494 GASTRIC MUCUS AND MUCOSAL INJURY. (Eng.) Glass, G. B. J. (New York Medical Coll., New York, NY). *Mater. Med. Pol.* 8(2):177-185; 1976.

4495 PROLIFERATION KINETICS OF GASTRIC SURFACE EPITHELIUM IN NORMAL AND DISEASED MUCOSA [Abstract]. (Eng.) Castrup, H. J. (Kliniken der Universitat Gottingen, Klinik und Poliklinik fur Allgemeinchirurgie, Gottingen, W. Germany). *Rend. Gastroenterol.* 9(1):76-77; 1977.

4496 QUANTITATION OF GASTRIN CELLS IN ENDOSCOPIC ANTRAL BIOPSIES BY IMMUNOFLUORESCENCE [Abstract]. (Eng.) Pera, A.; Crivelli, O.; Ferrari, A.; Babando, G.; Verme, G. (Divisione di Gastroenterologia dell'Ospedale Mauriziano Umberto I, Torino, Italy). *Rend. Gastroenterol.* 9(1):49-50; 1977.

4497 CONJUGATED DIHYDROXY BILE SALT INHIBITION OF GLUCOSE INFLUX IN RAT JEJUNUM IN VITRO.

(Eng.) Feldman, E. B.; Watt, R.; Feldman, D. S. (Medical Coll. Georgia, Augusta, GA 30902). *Am. J. Dig. Dis.* 22(5):415-418; 1977.

The effects of bile salts on intestinal glucose transfer and the effects of chemical and surgical bile diversion were studied in male rats. Radiolabeled glucose influx into the jejunum *in vitro* was studied in buffer and compared to taurodeoxycholate, taurochenodeoxycholate, taurocholate, and deoxycholate. The jejunum was obtained from intact, bile-diverted, and colestipol-treated rats and after x-irradiation. In untreated saline intubated or sham-operated rats, jejunal glucose influx in buffer alone was the same and did not change in the presence of the bile salts. Production of a complete bile fistula resulted in a 38% increase ($p<0.01$) of glucose influx from buffer. Addition of bile salts to jejunal segments from these bile-diverted rats resulted in a significant 40% decrease in glucose influx with conjugated dihydroxy sodium taurodeoxycholate (TDC, $0.02>p>0.01$). Because of the large standard error, the decreased glucose influx with sodium taurochenodeoxycholate was not statistically significant ($p=0.24$). Glucose influx rates with deoxycholate and conjugated trihydroxy sodium taurocholate did not differ significantly from the values in buffer. Jejunal glucose influx in colestipol-treated rats was one-third lower than that of intact untreated rats ($p<0.001$) and half that of bile fistula rats ($p<0.001$). However, the addition of TDC ($p<0.001$) and TCDC ($0.05>p>0.02$) to colestipol-treated rat jejunum significantly reduced glucose influx still further. Abdominal x-irradiation significantly decreased jejunal glucose influx from buffer in intact untreated ($p<0.001$), bile fistula ($0.05>p>0.02$), and colestipol-treated ($p<0.001$) rats. The data suggest that normal exposure to bile chronically inhibits jejunal glucose transport and that dihydroxy bile salts are responsible for this effect. They do not provide an explanation for the role of bile in the intestinal radiation syndrome.

4498 ACUTE AND CHRONIC EFFECTS OF ETHANOL ON FLUID TRANSPORT IN THE HUMAN SMALL INTESTINE.

(Eng.) Mekhjian, H. S.; May, E. S. (N-937 Univ. Hosp., The Ohio State Univ., 410 West 10th Ave., Columbus, OH 43210). *Gastroenterology* 72(6): 1280-1286; 1977.

The effect of acute and chronic administration of ethanol on jejunal and ileal water and electrolyte transport was studied in 13 healthy volunteers by the triple lumen intestinal perfusion technique. The acute perfusion of a glucose-free electrolyte solution containing 2-10 g/100 ml of ethanol in the jejunum or ileum did not change sodium or water transport. In contrast, the administration of a folate-deficient diet and ethanol for 2 weeks produced a marked reduction in sodium and water absorption or a small net secretion (control: $H_2O=0.91 \pm 0.06$ ml/min, Na=130 ± 8 µEq/min/30 cm intestine versus $H_2O=-0.13 \pm 0.14$ ml/min, Na=-20 ± 29 µEq/min/30 cm, $p<0.001$). These changes were not accompanied by a reduction in serum folate levels. The administration of ethanol with a folate-supplemente diet also produced significant changes in sodium an water transport (control: $H_2O=1.33 \pm 0.2$ ml/min, Na=185 ± 34 µEq/min/30 cm intestine versus $H_2O=0.48 \pm 0.17$ ml/min, Na=65 ± 16 µEq/min/30 cm intestine, $p<0.05$). It appears that the diarrhea seen in chronic alcoholics can be explained in part by the effect of ethanol on intestinal sodium transpor without any accompanying changes in serum folate levels.

4499 EFFECT OF GLYCOCHENODEOXYCHOLIC ACID ON UNIDIRECTIONAL TRANSEPITHELIAL FLUXES OF ELECTROLYTES IN THE PERFUSED HUMAN ILEUM.

(Eng.) Oddsson, E.; Rask-Madsen, J.; Krag, E. (Herlev Hosp Univ. Copenhagen, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12(2):199-204; 1977.

Perfusion studies of the terminal ileum were performed in 10 healthy volunteers to define the influence of a dihydroxy bile acid, glycochenodeoxy cholic acid (GCDC, 2.5 mM), on the mechanisms of electrolyte transport. GCDC caused significant decreases in water, sodium, potassium, and chloride absorption or increases in their secretion ($p<0.01$) but no change in bicarbonate transport. Net ion movement showed a linear relationship to net water movement, and the ion concentration in the fluid absorbed or secreted was identical to the ion concentration of the perfusate. During control perfusion, sodium was absorbed against a small chemical and a substantial electrical gradient, and chloride was absorbed against a chemical, but along an electrical, gradient. During GCDC perfusi sodium was secreted along a chemical and electrical gradient. Potassium secretion was enhanced, but the electrochemical gradient was unchanged. Chlori was secreted along a chemical, but against an electrical, gradient. In the control periods, the intestinal lumen was 10-20 mV negative relative to blood with a median value of -16 mV. GCDC did not influence the potential difference significantly. GCDC decreased the mucosa to serosa flux of chlorid The results support the existence of an active mechanism for sodium and chloride transfer, and a model for the GCDC effect is proposed.

4500 EFFECTS OF SYNTHETIC HUMAN GASTRIN I ON MOVEMENTS OF WATER, ELECTROLYTES, AND GLUCOSE ACROSS THE HUMAN SMALL INTESTINE.

(Eng.) Modigliani, R.; Mary, J. Y.; Bernier, J. J. (Hopita Saint-Lazare, 107 rue du Faubourg Saint Denis, 75010 Paris, France). *Gastroenterology* 71(6):978-984; 1976.

The effect of graded doses (0.125, 0.500, 1.00, and 2.00 µg/kg/hr) of i.v. synthetic human gastrin I (SHG) on jejunal transport of water, electrolytes, and glucose from a glucose-saline solution (soluti II) was studied in 12 healthy volunteers, using an intestinal perfusion technique with a proximal occluding balloon. SHG (≥0.500 µg/kg/hr) significant reduced water and electrolyte absorption; this effect was linearly related to the dose and reached 40-60% of basal absorption (and only 10% for glucose) with the highest dose. Insorption of sodium and water were significantly decreased by SHG. In an additional nine subjects, no effect of SHG (2 μg/kg/hr) was found on jejunal absorption from a mannitol-saline solution (solution I) and on ileal absorption from solutions I and II; in five additional subjects, SHG did not decrease jejunal transit time of intraluminal fluid. There was no increase in serum thyrocalcitonin during SHG infusion. It is proposed that SHG selectively depresses the glucose-stimulated sodium transport as suggested by the reduction of the rate of net sodium absorption per micromole of glucose absorbed during SHG infusion.

4501 EFFECTS OF SALINE INFUSION AND ACUTE METABOLIC ACIDOSIS AND ALKALOSIS ON WATER AND ELECTROLYTE TRANSPORT IN THE HUMAN COLON.

(Eng.) Crepeau, R.; Romeder, J. M.; Devroede, G.; Plante, G. E. (Centre Hospitalier Universitaire, Sherbrooke, Quebec, Canada). *Can. J. Physiol. Pharmacol.* 55(1): 13-20; 1977.

The respective contributions of the kidney and the colon to acid-base and electrolyte balance were studied in eight healthy male volunteers who underwent simultaneous renal clearance studies, and colonic perfusion with a 0.9% saline or 7.2% mannitol solution, during metabolic alkalosis and acidosis, extracellular volume expansion, and control conditions. These acid-base conditions had no influence on electrolyte transport in the colon. In the urine, preferential loss of chloride over sodium averaged 81, 143 ($p<0.001$), and 141 ($p<0.05$) μEq/min, during control, metabolic acidosis, and extracellular volume expansion conditions, resp. During alkalosis, more sodium than chloride was lost (146 μEq/min; $p<0.001$). Colonic pH averaged 7.41 during saline and 6.75 ($p<0.005$) during mannitol perfusion. Titratable acid was not produced in the colon during saline perfusion, and averaged 18 μEq/min during mannitol perfusion. Urinary titratable acid increased from 19 to 25 μEq/min ($p<0.01$) during volume expansion. With saline perfusion, bicarbonate secretion rate in the colon rose from 249 μEq/min during control conditions to 289 μEq/min during metabolic alkalosis ($p<0.05$). More bicarbonate was excreted in the urine during alkalosis when mannitol was introduced in the colon (243 μEq/min) than when saline was perfused (152 μEq/min; $p<0.05$). This study indicates that the response of the human colon is trivial compared with that of the kidney during acute changes in acid-base balance.

4502 UPTAKE OF K^+ BY FROG GASTRIC MUCOSA FROM SUBMUCOSAL SIDE AND ACID SECRETORY RATE.

(Eng.) Takeguchi, N.; Horikoshi, I.; Hattori, M. (Faculty Pharmaceutical Sciences, Univ. Toyama, Toyama, Japan). *Am. J. Physiol.* 232(3):E294-E297; 1977.

The dependence of the K^+ gastric mucosal content, transmucosal potential difference, and acid secretory rate on the K^+ concentration in the submucosal solution was investigated in frogs (*Rana catesbeiana*) The K^+ content (K^+) in gastric mucosa was measured as a function of the submucosal K^+ concentration ($[K^+{}_{sm}]$) in the absence of K^+ on the mucosal side. The (K^+) in HCO_3 buffer with 95% O_2-5% CO_2 gas showed that the removal of external K^+ induced a 27% loss from the control value of 5 mM $K^+{}_{sm}$, that there was no linear relation between (K^+) and $[K^+{}_{sm}]$, and that the change in the (K^+) versus $[K^+_{sm}]$ was hyperbolic. This indicates that there are two different types of K^+ in the mucosa: bound and free.

4503 THE RELATIVE TRANSFER RATES FOR SODIUM AND XENON FROM GUT LUMEN TO PLASMA IN MAN.

(Eng.) Love, A. H. G.; Chen, L. C.; Reeve, J.; Veall, N. (Dept. Medicine, Queen's Univ. Belfast, Belfast, Northern Ireland). *Clin. Sci. Mol. Med.* 52(3):249-254; 1977.

The unidirectional transfer rate of sodium from gut lumen to plasma was compared with that of the tracer ^{133}Xe to test the hypothesis that mucosal blood flow to the small intestine may be the dominant rate-limiting factor that determines the unidirectional transfer of sodium from gut lumen to plasma. A whole-gut perfusion technique was used. The calculated transit-time spectra for sodium and xenon across the gut mucosa did not differ significantly either in mean transit time (6.05 and 6.60 min, resp.) or, for the first 15 min, in shape. The results support the hypothesis that the rate of transfer of sodium from the small intestinal lumen is limited by blood flow, and that this reduction in cholera patients reflects a reduction in mucosal blood flow. There is increasing evidence that suggests that the specific effect of cholera toxin is to promote a secretory mechanism. Therefore, the reduction of mucosal blood flow in cholera patients would not be of primary importance in the pathogenesis of cholera diarrhea.

4504 ELECTRICAL POTENTIAL PROFILE IN RABBIT ILEUM: ROLE OF RHEOGENIC Na TRANSPORT.

(Eng.) Rose, R. C.; Nahrwold, D. L.; Koch, M. J. (Milton S. Hershey Medical Center, Pennsylvania State Univ., Coll. Medicine, Hershey, PA 17033). *Am. J. Physiol.* 232(1):E5-E12; 1977.

The electrical potential profile of rabbit ileum was investigated *in vitro* by a microelectrode technique to determine if this profile is consistent with rheogenic ion transport. The transmural electrical potential difference (PD), designated ψms, was immediately reduced by 60% upon cooling the tissue from 37 to 7 C; the PD across the mucosal membrane (transmucosal PD, ψmc) was simultaneously reduced by 37%. These electrical changes could not be attributed to alterations in either transmembrane ion concentration gradients or total tissue conductance. The ψmc and ψms may have substantial values even after the concentration gradients of Na and K across the cell membrane are eliminated, provided that active transport mechanisms are still operative. Conversely, in the presence of approximately normal transmembrane ion concentration gradients, but when active transport mechanisms have been inhibited, ψmc is reduced by 45% and ψms is zero. These observations are consistent with a model of electrolyte transport in which ψms and the normal transmembrane cation concentration gradients are established by rheogenic active transport of Na out of the cell. The ψmc is generated both by rheogenic active Na transport and by cation concentration gradients that exist across the cell membrane.

4505 ACTIVE SODIUM TRANSPORT AND THE ELECTROPHYSIOLOGY OF RABBIT COLON. (Eng.)

Schultz, S. G.; Frizzell, R. A.; Nellans, H. N. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *J. Membrane Biol.* 33(3/4):351-384; 1977.

Using microelectrode techniques, the electrophysiologic properties of rabbit colonic epithelial cells were investigated. Under open-circuit conditions, the transepithelial electrical potential difference (PD) averaged 20 mV, serosa positive, and the intracellular electrical potential (ψ_{mc}) averaged -32 mV, cell interior negative with respect to the mucosal solution; under short-circuit conditions, ψ_{mc} averaged -46 mV. The addition of amiloride to the mucosal solution abolished the transepithelial PD and active Na transport, and ψ_{mc} was hyperpolarized to an average value of -53 mV. These results indicate that Na entry into the mucosal cell is a conductive process that normally depolarizes ψ_{mc}. The data were interpreted using a double-membrane equivalent electrical circuit model of the "active Na transport pathway" involving two voltage-independent electromotive forces (emf's) and two voltage-independent resistances arrayed in series. The observations are consistent with the notions that the emf's and resistances across the mucosal and basolateral membranes are determined predominantly by the emf (64 mV) and resistance of the Na entry process and the emf (53 mV) and resistance of the process responsible for active Na extrusion across the basolateral membranes. That is, the electrophysiological properties of the cell appear to be determined solely by the properties and processes responsible for transcellular active Na transport. The emf of Na entry is consistent with the proposal that the Na activity in the intracellular transport pool is approximately one-tenth that in the mucosal solution, or about 14 mM. In the presence of amiloride, the transcellular conductance is essentially abolished, and the total tissue conductance is the result of ionic diffusion through paracellular pathways. The negative intracellular potential is due primarily to the presence of a low-resistance paracellular "shunt" pathway that permits electrical coupling between the emf at the basolateral membrane and the potential difference across the mucosal membrane; in the absence of this shunt, the "well-type" electrical potential profile characteristic of rabbit colonic cells would be converted into a "staircase-type" profile similar to those reported for frog skin and toad urinary bladder.

4506 TRANSFER OF SODIUM AND WATER THROUGH ISOLATED RAT COLONIC MUCOSA UNDER THE INFLUENCE OF DEOXYCHOLATE AND OXYPHENISATIN. (Eng.)

Wanitschke, R.; Nell, G.; Rummel, W.; Specht, W. (I. Medizinische Klinik, Universitat Mainz, Langenbeckstrasse 1, D-6500 Mainz, W. Germany). *Naunyn Schmiedeberg's Arch. Pharmacol.* 297(2):185-190; 19

The mechanism by which oxyphenisatin (OP) and bile acids inhibit intestinal water and electrolyte absorption and induce net fluid and electrolyte transfer into the lumen was studied in an everted sac preparation of stripped rat colon. OP (10^{-5} M mucosal side) and deoxycholate (3×10^{-4} M, mucosa side) completely blocked net water and sodium absorption. Net movements from the serosal to the mucosal side were not induced by higher concentrations of the drugs. Unidirectional sodium movemen in both directions were increased by OP and deoxycholate. Sodium flux from mucosa to serosa was increased from a control of 2.40 ± 0.15 to 3.05 ± 0.20 mEq/hr/g by deoxycholate and to 3.70 ± 0.18 mEq/hr/g by OP; sodium flux in the opposite direct was increased from a control of 1.08 ± 0.32 to 3.1 ± 0.35 mEq/hr/g by deoxycholate and to 3.65 ± 0.45 mEq/hr/g by OP. The effect of deoxycholate on the sodium flux from the serosal to the mucosal side w reversible. The potassium content of the mucosal epithelium was unchanged by the two agents. The integrity of the epithelium, as judged by light microscopy, was not disturbed by either drug under the experimental conditions. It is concluded that deoxycholate and OP do not interfere with active transport mechanism, but increase the permeability of the epithelium to sodium.

4507 EFFECTS OF GLUCAGON ON CANINE INTESTINA SODIUM AND WATER FLUXES AND REGIONAL BLOOD FLOW. (Eng.)

MacFerran, S. N.; Mailman, D (Biology Dept., Univ. Houston, Houston, TX 77004) *J. Physiol. (London)* 266(1):1-12; 1977.

The possibility that glucagon alters gut absorpti by altering capillary blood pressure through its vasodilator activity was examined in dogs. Glucagon (0.05 or 0.5 µg/kg/min) was infused into a mesenteric artery of an ileal segment, from which transport was measured (direct infusion), or into a mesenteric artery of an adjacent non-perfused segment (indirect infusion). Unidirectional Na and H_2O fluxes, arterial and mesenteric vein pressures, and total and absorptive site blood flows were measured. Direct glucagon infusion increased the absorptive and secretory fluxes of Na and H_2O and absorptive site blood flow, and decreased absorptive site resistance and arterial and mesenteric vein pressure. Indirect glucagon infusion had the opposite effects. Neither the direct arterial infusion of histamine (0.1-53 µg/kg/min) nor the i.v. infusion of glucose (0.2 g/min), insulin (0.1 U/kg), or glucose plus insulin mimicked the effects of glucagon. The unidirectional secretory and absorptive fluxes of both Na and H_2O were linearly related to the calculated capillary pressure during glucagon infusion. It is concluded that the effects of glucagon on gut transport are due to effects exerted through the cardiovascular system.

4508 SUCROSE ABSORPTION BY THE RAT SMALL INTESTINE IN VIVO AND IN VITRO. (Eng.)

Davidson, R. E.; Leese, H. J. (Dept. Biology, Univ. York, York YO1 5DD, England). *J. Physiol. (London)* 267(1):237-248; 1977.

Previous evidence that the fructose derived from sucrose elevates plasma triglyceride levels and may predispose individuals to ischemic heart disease and obesity led to studies in which the absorption of glucose and of fructose derived from sucrose was investigated using *in vitro* and *in vivo* loops of the Wistar rat jejunum. At low sucrose concentrations (1 and 10 mM) glucose appeared in the serosal compartment of the *in vitro* preparation at a faster rate than did fructose, but at high sucrose concentrations (50 and 100 mM) the rates of serosal transfer of the two sugars were similar. Glucose and fructose appeared in the mucosal compartment, with the rate of fructose appearance exceeding that of glucose, at all the sucrose concentrations studied. Phlorizin (5×10^{-5} M) added to the *in vitro* preparation abolished the serosal transfer of glucose derived from 50 mM sucrose, and reduced that of fructose by 75%. In the absence of sodium ions, the *in vitro* preparation failed to transfer glucose and fructose derived from 50 mM sucrose into the serosal compartment. Glucose was actively accumulated in the whole gut wall of the *in vivo* preparation to concentrations higher than those in the plasma at 50 and 100 mM, but not at 10 mM sucrose concentrations. Fructose was also actively accumulated to about half the extent of glucose, but reached tissue concentrations greater than those in the plasma at each sucrose concentration. The whole-wall concentrations of glucose and fructose derived from sucrose added to the lumen continued to rise when the blood supply to the *in vivo* preparation was terminated. No increase in the *in vivo* whole-wall concentrations of glucose and fructose were detected when sucrose was added to the lumen together with concentrations of glucose sufficient to saturate the monosaccharide transport systems. The results suggest that disaccharide hydrolysis and the resulting hexose transfer are sequential and separate events.

4509 PANCREATIC EXTRACT AND THE INTESTINAL UPTAKE OF VITAMIN B_{12}. II. INHIBITORY EFFECT OF TRYPSIN AND TRYPSINOGEN. (Eng.) von der Lippe, G.; Andersen, K. J.; Morkrid, L.; Schjonsby, H. (Haukeland sykehus, N-5016 Bergen, Norway). *Scand. J. Gastroenterol.* 12(2):177-182; 1977.

The pancreatic factors responsible for the ability of pancreatic extract, rat pancreatic juice, and human duodenal juice to inhibit the uptake of intrinsic factor (IF)-bound vitamin B_{12} by perfused rat intestinal segments were investigated. Neither nonradioactive vitamin B_{12} nor nonpancreatic protein reduced $^{57}CoB_{12}$ uptake ($p>0.5$ and $p>0.1$, resp.) by small intestinal segments. Trypsin (1.5 mg/ml) and trypsinogen (5.0 mg/ml) significantly reduced the mean intestinal uptake of $^{57}CoB_{12}$-IF, whereas chymotrypsin (20.0 mg/ml) had no significant effect. The uptake after perfusion with only 1.5 mg/ml trypsinogen (21.2 ± 3.3 pg $^{57}CoB_{12}$/cm intestine) was not significantly different from the control uptake (21.7 ± 3.9 pg/cm). When soybean trypsin inhibitor was added to pancreatic extract, the mean intestinal uptake (18.6 ± 1.0 pg/cm) was significantly lower than the control uptake (29.1 ± 2.7 pg/cm, $p<0.01$). Detrypsinized pancreatic extract reduced the uptake from 26.2 ± 4.3 (control) to 15.5 ± 2.1 pg/cm, ($p<0.02$). When trypsin was inactivated by soybean trypsin inhibitor, the mean intestinal uptake was not significantly different from the control. The results suggest that the pancreatic extract contains several factors capable of inhibiting the intestinal uptake of IF-bound vitamin B_{12}.

4510 PANCREATIC EXTRACT AND THE INTESTINAL UPTAKE OF VITAMIN B_{12}. III. STIMULATORY EFFECT IN THE PRESENCE OF A NON-INTRINSIC FACTOR VITAMIN B_{12} BINDER. (Eng.) von der Lippe, G.; Andersen, K. J.; Schjonsby, H. (Haukeland sykehus, N-5016 Bergen, Norway). *Scand. J. Gastroenterol.* 12(2):183-187; 1977.

The mechanism by which pancreatic extract (PE) corrects the malabsorption of vitamin B_{12} in chronic pancreatic insufficiency (CPI) was investigated in male Wistar rats. The p.o. administration of PE (100 mg) had no effect on the pH in the proximal, middle, or distal small intestine. PE did not stimulate the uptake of unbound $^{57}CoB_{12}$ by perfused rat intestinal segments. Preincubation of $^{57}CoB_{12}$ bound to intrinsic factor ($^{57}CoB_{12}$-IF) with a non-IF B_{12}-binder from human saliva (R-binder) reduced the intestinal uptake of $^{57}CoB_{12}$ from 18.5 ± 3.4 pg/cm intestine to 7.8 ± 1.6 pg/cm ($p<0.02$). PE abolished this inhibitory effect ($p<0.05$). The results indicate that PE corrects the malabsorption of vitamin B_{12} in chronic pancreatic insufficiency by an effect on non-IF B_{12} binders.

4511 VARIATIONS IN INTESTINAL ABSORPTION. THE AMBIENT: ORAL XYLOSE TESTS IN CHILDREN. (Ita.) Ciampolini, M.; Adami-Lami Conti, C.; Muzzarelli, D. (Pediatric Clinic, Univ. Florence, Florence, Italy). *Minerva Gastroenterol.* 23(1):1-4; 1977.

4512 IRON ABSORPTION IN MALNUTRITION--EXPERIMENTAL ASSAY. (Por.) Goncalves, A. L.; Faggioni, L. G.; Jorge, S. M.; Granzotti, J. A.; Iazigi, N.; Santoro, J. R. (Hospital das Clinicas-Setor de Pediatrica, Rua Bernardino de Campos, 1000, 14100-Ribeirao Preto, Sao Paulo, Brazil). *Arq. Gastroenterol.* 14(1):37-40; 1977.

4513 EFFECT OF SODIUM ON THE ACTIVE TRANSPORT OF SUGAR IN THE RAT SMALL INTESTINE [Abstract]. (Ger.) Forster, H.; Beyer, R. (Zentrum der Biologischen Chemie, Theodor-Stern-Kai 7, D-6000 Frankfurt, W. Germany). *Hoppe Seylers Z. Physiol. Chem.* 358(3):233; 1977.

4514 PRESSURE PROFILE OF ESOPHAGEAL PERISTALSIS IN NORMAL HUMANS AS MEASURED BY DIRECT INTRAESOPHAGEAL TRANSDUCERS.

(Eng.) Humphries, T. J.; Castell, D. O. (Naval Regional Medical Center, Philadelphia, PA 19145). *Am. J. Dig. Dis.* 22(7): 641-645; 1977.

The pressure profile of esophageal peristalsis was studied in healthy young men using an intraesophageal transducer assembly. The amplitude of peristaltic contractions following wet swallows was determined at intervals along the esophagus from the lower esophageal sphincter (LES) to the upper esophageal sphincter (UES). The amplitude profile revealed a trough of significantly decreased ($p<0.05$) amplitude at 17.5-20.0 cm above the LES. The change in pressure per unit time (dp/dt) also produced a profile with a significant decrease ($p<0.01$) in the upper esophagus; it correlated ($r=0.91$, $p<0.001$) with the amplitude profile. The mean velocity of the peristaltic wave in the upper esophagus varied from 2.92 ± 0.19 to 3.29 ± 0.36 cm/sec. In the distal esophagus, the mean velocity increased significantly ($p<0.01$) to 4.98 ± 0.38 cm/sec at 7.5 cm above the LES and then fell significantly ($p<0.05$) to 2.15 ± 0.27 cm/sec at 2.5 cm above the LES. The dp/dt could possibly be used in the early detection of esophageal diseases.

4515 TEMPERATURE DEPENDENCE OF RESPONSES OF ESOPHAGEAL SMOOTH MUSCLE TO ELECTRICAL FIELD STIMULATION.

(Eng.) de Carle, D. J.; Szabo, A. C.; Christensen, J. (Dept. Internal Medicine, Univ. Iowa, Iowa City, IA 52242). *Am. J. Physiol.* 232(4):E432-E436; 1977.

The effect of temperature on swallowing-induced peristalsis was investigated in the esophagus of the opossum. Strips of smooth muscle, cut transversely from the smooth muscle segment of the esophagus, were superfused with oxygenated Krebs-Ringer solution at 37 C in a system that allowed electrical field stimulation of the intrinsic nerves. Trains (3- to 5-sec) of rectangular pulses (0.5-msec long at 10 Hz) were delivered at 30-sec intervals at supramaximal maximal current strength. In strips from the esophageal body, a twitch occurred at the end of each train with a particular latency, the off response. Strips from the esophagogastric sphincter relaxed during the train. Temperature varied above and below 37 C (18-40 C) to observe the temperature dependence of the responses. Latency of the off-response varied exponentially with temperature. Amplitude of the off response showed a linear decline with changes in temperature, both above and below 35 C, the zero intercepts being 19.6 and 42.3 C, resp. Amplitude of relaxation of strips from the junction varied little between 20 and 37 C but declined sharply beyond those limits, the zero intercepts being 14.2 and 42 C, resp. These studies show that the operation of the circular layer of smooth muscle in the esophageal body is sensitive to changes in temperature.

4516 INFLUENCE OF VAGAL COOLING ON ESOPHAGEAL FUNCTION.

(Eng.) Ryan, J.; Snape, W. J., Jr.; Cohen, S. (Temple Univ. Sch. Medicine and Univ Pennsylvania Hosp., Philadelphia, PA). *Am. J. Physiol.* 232(2):E159-E-164; 1977.

The effect of decreased vagal activity on the esophageal peristalsis and lower esophageal sphincter (LES) relaxation associated with pharyngeal stimulation (PS) and esophageal balloon distension (ED) was studied in opossums. The cervical vagi were exposed and cooled (individually and bilaterally) to 3 C using dry ice and alcohol-chilled saline Unilateral vagal cooling had no effect on the esophageal peristalsis or LES relaxation associated wit PS or ED. Similarly, bilateral vagal cooling did not alter the peristalsis and sphincter relaxation induced by ED. Bilateral vagal cooling, however, significantly decreased the incidence of peristalsi and the sphincter relaxation associated with PS (incidence of peristalsis reduced from a control level of 99.1 ± 0.4% to 78.0 ± 2.6%; LES relaxation reduced from 98.0 ± 0.7% to 37.3 ± 4.8%; $p<0.01$ and $p<0.001$, resp.). The effect of unilater and bilateral vagotomy on esophageal function was also examined. Neither right nor left cervical vagotomy affected esophageal peristalsis or LES relaxation, regardless of the model of stimulation Bilateral vagotomy, however, diminished the esophageal response to PS but was without effect on the peristalsis and LES relaxation produced in respons to ED. It is concluded that the vagus nerve is of primary importance in regulating the esophageal response to PS and that local neuromuscular factors within the esophageal wall are sufficient to initiate and maintain an esophageal response to distension.

4517 UPPER ESOPHAGEAL RESPONSES TO INTRALUMI DISTENTION IN MAN.

(Eng.) Enzmann, D. Harell, G. S.; Zboralske, F. F. (Stanford Univ. Sc Medicine, Stanford, CA 94305). *Gastroenterology* 72(6):1292-1298; 1977.

The site(s) of elicitation and origin of secondary peristalsis in the human esophagus were studied, a the upper esophageal sphincter (UES) and proximal esophageal body responses accompanying intralumina distention were characterized. In seven normal su jects, an intraluminal transducer probe manometric recorded the UES and 5- and 10-cm levels of the es ageal body. A second probe with a balloon attache 2 cm above the proximal strain gauge was located s that the balloon was 3 and 4 cm below the UES and four distentions were done. The balloon probe was moved in 2-cm increments (four distensions at each site) until lower esophageal sphincter pressures were recorded. No secondary peristalsis occurred after distention in the proximal 6 cm. The incidence of secondary peristalsis increased as the di tention site moved distally. Sixty-nine percent o secondary peristaltic waves originated in the esop ageal body proximal to the distention site. The U pressure significantly increased over resting pres sure (augmentation) during 63% of distentions. Th esophagus proximal to the balloon and below the UE usually responded to distention with augmentation. Augmentation of the UES and proximal esophageal body in response to esophageal intraluminal distention and the resultant initiation of secondary peristalsis above the distention site comprise a highly integrated pressure barrier to esophagopharyngeal reflux.

4518 THE EFFECT OF PRESSURE CHANGES INSIDE THE ANTRUM ON LOWER ESOPHAGEAL SPHINCTER (LES) PRESSURE IN MAN AND DOG. (Eng.) Jennewein, H. M.; Hummelt, H.; Siewert, R.; Weiser, F.; Waldeck, F. (Klinik und Poliklinik fur Allgemeinchirurgie, Universitat Gottingen, Gottingen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 23(6):449-454; 1976.

The pressure change inside the lower esophageal sphincter (LES) in response to pressure changes inside the antrum was investigated in men (6) and in dogs (16 beagle bitches) with antral pouches. A pressure of 20 cm H_2O inside the antrum produced an increase in LES pressure in the dog of 14 ± 7 mm Hg ($p<0.01$) or 43% and simultaneously produced a rise in blood gastrin concentration of 29 ± 23 fmol/ml ($p<0.01$). An antral pressure of 80 cm30 cm H_2O led to a decrease of 26 ± 12 mm Hg ($p<0.01$) or 67% in LES pressure. Truncal vagotomy in dogs with innervated antral pouches abolished the excitory and inhibitory effects on LES pressure of the 20 cm H_2O antral pressure, but gastrin concentration still increased by 19 ± 16 fmol/ml ($p<0.05$). In four dogs with denervated antral pouches, antral pressure changes did not influence LES pressure or gastrin response significantly. LES pressure in dogs responded to electrical vagal stimulation. Atropine (0.5 mg/kg, i.v.) abolished the initial contraction (at 20 pulses/sec) and the excitatory effect (at 0.5 pulses/sec) in dogs. In man, a short antral pressure increase (50 cm H_2O for 30 sec) produced a decrease of LES pressure from 14 ± 3.4 mm Hg to 5.2 ± 1.4 mm Hg ($p<0.01$) for about 1 min. This effect was not seen in patients after selective proximal vagotomy. It is concluded that a pressure increase inside the antrum effects LES pressure both in man and dogs.

4519 EFFECT OF CHOLECYSTOKININ-OCTAPEPTIDE ON LOWER ESOPHAGEAL SPHINCTER. (Eng.) Behar, J.; Biancani, P. (Rhode Island Hosp., 539 Eddy St., Providence, RI 02902). *Gastroenterology* 73(1):56-61; 1977.

The effect of cholecystokinin-octapeptide (CCK-OP) on the lower esophageal sphincter (LES) was studied in 50 cats *in vivo*. CCK-OP caused a dose-dependent fall in LES pressures in all but four animals. Maximal sphincter relaxation was obtained with 200-400 ng of CCK-OP per kg of body weight. Atropine sulfate (30 μg/kg) and/or hexamethonium (40 mg/kg), or adrenergic blocking agents phentolamine (1 mg/kg) or propranolol (1 mg/kg), in doses that completely inhibit the action of maximal doses of their respective agonists, failed to block the CCK-OP effect. Tetrodotoxin, however, in doses that denervated the LES (12-18 μg/kg) antagonized the CCK-OP-induced sphincter relaxation. In these tetrodotoxin-treated animals, CCK-OP produced LES contraction similar to that observed after pentagastrin. These results suggest that CCK-OP stimulates the postganglionic nonadrenergic, noncholinergic inhibitory neurons responsible for sphincter relaxation. CCK-OP also stimulates the circular muscle by direct action, causing LES contraction. The latter becomes apparent when the innervation of the LES is abolished by tetrodotoxin.

4520 EFFECT OF DOPAMINE ON ESOPHAGEAL MOTOR FUNCTION. (Eng.) Mukhopadhyay, A. K.; Weisbrodt, N. (Univ. Texas Medical Sch., Houston, TX 77030). *Am. J. Physiol.* 232(1):E19-E24; 1977.

The receptors involved in the dopamine response in esophageal smooth muscle were characterized. The i.v. administration of dopamine in opossums produced a dose-dependent decrease in lower esophageal sphincter pressure and a dose-dependent increase in contractile activity of the body of the esophagus. The threshold dose of dopamine was 0.25 μg/kg, and the effect reached a plateau at about 6 μg/kg, A dose of 6 μg/kg of dopamine produced an 83% ± 3% reduction in the lower esophageal sphincter pressure and 12 ± 1 contractions in the body of the esophagus within 5 min. Atropine (30 μg/kg), phentolamine (4 mg/kg), propranolol (2 mg/kg), and bilateral cervical vagotomy did not modify the effect of dopamine. Both haloperidol (5 mg/kg) and bulbocapnine (5 mg/kg) potently antagonized the effect of dopamine ($p<0.001$ in both cases). The amplitude of esophageal contraction in the lower esophagus in response to pharyngeal stimulation and esophageal distention was significantly increased after the administration of haloperidol. It is concluded that the i.v. administration of dopamine has potent effects on the motor function of the lower esophageal sphincter and the body of the esophagus. The effect of dopamine is not mediated via the vagal centers in the brain or cholinergic muscarinic and adrenergic receptors. The response of the smooth muscle segment of opossum esophagus to i.v. dopamine is mediated via specific dopamine receptors. The inhibitory dopamine receptors may play a physiological role in controlling the amplitude of esophageal contractions.

4521 LOWER ESOPHAGEAL SPHINCTER AND GASTRIC ACID RESPONSES TO INTRAVENOUS INFUSIONS OF SYNTHETIC HUMAN GASTRIN I HEPTADECAPEPTIDE. (Eng.) Freeland, G. R.; Higgs, R. H.; Castell, D. O.; McGuigan, J. E. (Naval Regional Medical Center, Philadelphia, PA 19145). *Gastroenterology* 71(4):570-574; 1976.

To determine whether the increased serum gastrin levels observed after feeding are involved in the control of lower esophageal sphincter (LES) pressure, human gastrin I heptadecapeptide (HGH) was administered to seven volunteers, and serum gastrin concentrations and LES pressure responses and gastric acid output were measured. HGH infusion (0.06 μg/kg hr, i.v.) increased LES pressure significantly, from a basal value of 16.4 ± 0.3 mm Hg to 22.4 ± 3.3 mm Hg at 90 min ($p<0.05$); LES pressure decreased to 17.5 ± 2.9 mm Hg 15 min after the infusion was stopped. Concurrently, gastric acid output increased insignificantly from a mean basal value of 2.28 ± 0.58 mEq/15 min to 5.15 ± 2.11 at 90 min. Serum gastrin levels increased significantly from a mean basal value of 86 ± 3 pg/ml to 116 ± 17 pg/ml at 75 min ($p<0.05$) and 110 ± 12 pg/ml at 90 min. The infusion of a higher level of HGH (0.12 µg/kg hr) also produced significant increases in LES pressure ($p<0.01$) and serum gastrin output ($p<0.01$); the gastric acid output increased significantly from a basal level of 1.99 ± 0.75 mEq/15 min to 5.08 ± 2.37 and 5.06 ± 0.87 mEq/15 min ($p<0.02$) at 75 and 90 min, resp. The infusion of 0.25 µg/kg/hr HGH produced progressively greater increases in LES pressure ($p<0.05$), gastric acid output ($p<0.01$), and serum gastrin concentrations ($p<0.01$). The peak serum gastrin level occurred 30 min after ingestion of a protein meal, increasing to 108 ± 14 pg/ml from a basal level of 62 ± 4 pg/ml ($p<0.05$). LES pressure increased concurrently and reached a peak 35 min after ingestion of the meal to 27.1 ± 4.0 mm Hg from a basal level of 17.0 ± 0.3 mm Hg ($p<0.05$). The results suggest that although increases in serum gastrin concentration may contribute to increases in LES pressure seen after feeding, the increase in LES pressure produced by feeding cannot be explained exclusively on the basis of endogenous gastrin release.

4522 EFFECT OF MOTILIN ON THE LOWER ESOPHAGEAL SPHINCTER OF THE OPOSSUM.

(Eng.) Gutierrez, J. G.; Thanik, K. D.; Chey, W. Y.; Yajima, H. (Genesee Hosp., 224 Alexander St., Rochester, NY 14607). *Am. J. Dig. Dis.* 22(5):402-405; 1977.

The effect of Yajima's synthetic motilin on the lower esophageal sphincter (LES) of the opossum was studied, and its potency was compared to that of gastrin and its interaction with secretin examined. Dose-response curves for the LES were constructed from the i.v. bolus injection of graded doses of motilin and gastrin alone and motilin given against a background infusion of secretin. The smallest dose of motilin that elicited a significant response was 0.05 µg/kg, and the highest response was observed with the highest dose used (1.0 µg/kg). Over a wide dose range, both motilin and gastrin were equally potent in stimulating the LES, and secretin caused inhibition of the LES pressure response to motilin. It is concluded that (1) motilin is a potent stimulant of the LES, (2) this response is dose dependent, (3) the potency of motilin is similar to that of gastrin, and (4) secretin counteracts the effect of motilin on the LES.

4523 EFFECT OF PENTAGASTRIN INFUSION ON GASTROESOPHAGEAL MANOMETRY AND REFLUX STATUS BEFORE AND AFTER ESOPHAGOGASTRECTOMY.

(Eng.) Moossa, A. R.; Hall, W.; Wood, R. A. B.; Cooley, G. R.; Skinner, D. B. (Dept. Surgery, Univ. Chicago, Pritzker Sch. Medicine, 950 E. 59th St., Chicago, IL 60637). *Am. J. Surg.* 133(1):23-28; 1977.

To elucidate the nature of the lower esophageal sphincter, the pressure profile, functional integrity, and response to pentagastrin of the lower esophagus were studied in Rhesus monkeys. The effect of replacement of the distal esophageal segment by a sleeve of stomach was also assessed. Five of eight animals were determined to be nonrefluxers, and these animals had a mean manometrically determined, preoperative high-pressure-zone (HPZ) pressure of 8.9 ± 0.85 mm Hg; three monkeys with reflux had a mean HPZ pressure of 6.6 ± 0.59 mm Hg. During a continuous pentagastrin (0.25 µg/kg/hr or 0.75 µg/kg/hr) infusion, the lower esophageal pressure increased rapidly at the start of infusion and reached a peak between 3 and 15 min; lower esophageal pressure increased from a baseline of 8.3 ± 0.75 mm Hg to a peak of 12.0 ± 0.86 mm Hg with the lower rate of infusion. Postoperatively, the response of all animals to pentagastr was similar to that noted preoperatively. Neither operation nor pentagastrin infusion altered the reflux status of any animal, all being nonrefluxer on every postoperative test. It is concluded that the ability to respond to pentagastrin infusion as a physiologic sphincter is a property of all of the upper gastrointestinal tract.

4524 EFFECT OF VASOACTIVE INTESTINAL POLYPEPT (VIP) ON THE LOWER ESOPHAGEAL SPHINCTER PRESSURE (LESP).

(Eng.) Rattan, S.; Said, S. I.; Goyal, R. K. (Univ. Texas Health Science Center, 5323 Harry Hines Blvd., Dallas, TX 75235). *Proc. Soc. Exp. Biol. Med.* 155(1):40-43; 1977.

The effect of vasoactive intestinal polypeptide (V on the lower esophageal sphincter (LES) was studie in anesthetized opposums. The i.v. administration of VIP at doses $\geq$0.25 µg/kg caused a dose-related fall in LES pressure. A dose of 8 µg/kg produced "maximal" fall of 36.8 ± 2.9 mm Hg (80.5 ± 4.5%) i sphincter pressure. The effect of VIP (8 µg/kg) was not antagonized by tetrodotoxin in doses that antagonized neural activity in the LES (10-40 µg/k Propranolol (1 mg/kg, i.v.) also failed to antagonize this inhibitory effect of VIP. These studies show that VIP exerts an inhibitory effect on the LES that may be due to a direct action on the sphin ter muscle.

4525 EXCITATION CONDUCTION IN AUERBACH'S PLEX OF RABBIT SMALL INTESTINE.

(Eng.) Yokoyama, S.; Ozaki, T.; Kajitsuka, T. (Fukushima Medical Coll., Fukushima, Japan). *Am. J. Physiol.* 232 (2):E100-E108; 1977.

Excitation conduction in Auerbach's plexus was investigated in the rabbit small intestine by analyzing its evoked potentials as the response to a single electrical stimulus given to this plexus. When the conduction distance was 1 mm, two spike waves were recorded. Conduction velocities of ner impulses were 0.3-0.5 msec, and chronaxie was 0.06-0.11 msec. When the distance between stimulating and recording electrodes was further increased, evoked potential waves became multiple and small, until beyond 15 mm in the longitudinal direction and beyond 3 mm in the circular direction they could no longer be recorded. Evoked potentials recorded at a distance >2 mm were reduced in their amplitude, and some potential waves were abolished after repeated stimulation with high frequencies (>50/sec), hexamethonium (10^{-4} g/ml) application, and a lack of oxygen. It is concluded that in Auerbach's plexus, nerve impulses spread through multiple pathways, conducting mainly on the longitudinal axis of the small intestine, and that some impulses make synaptic transmission at ganglia.

4526 EXCITATION CONDUCTION IN MEISSNER'S PLEXUS OF RABBIT SMALL INTESTINE. (Eng.) Yokoyama, S.; Ozaki, T.; Kajitsuka, T. (Fukushima Medical Coll., Fukushima, Japan). *Am. J. Physiol.* 232 (2):E109-E113; 1977.

Excitation conduction in Meissner's plexus was investigated in the rabbit small intestine by analyzing the records of potentials evoked by a single electrical stimulus applied to this plexus. Experiments were performed on the Meissner's plexus that remained attached to the circular muscle after the longitudinal muscle and mucous membrane were removed from intestinal segment. Conduction velocities of nerve impulses were 0.3-0.7 msec, chronaxie of the nerve bundle was 0.06-0.12 msec, while the distance between the stimulating and recording electrodes was increased, the latency of the evoked potentials was prolonged, the number increased, and the amplitude decreased; no potentials could be recorded when the distance was 4 mm. Evoked potentials recorded at relatively long conduction distance were reduced in amplitude or abolished after a repeated stimulation with high frequencies (>50/sec) after hexamethonium application (10^{-4} g/ml), and in a state of lack of oxygen. Nerve impulses appear to spread through multiple pathways and make synaptic transmission at a relatively short conduction distance in Meissner's plexus.

4527 CHARACTERISTICS OF THE RELAXANT RESPONSE OF ADENOSINE AND ITS ANALOGS IN INTESTINAL SMOOTH MUSCLE. (Eng.) McKenzie, S. G.; Frew, R.; Bar, H. P. (Dept. Pharmacology, Univ. Alberta, Edmonton, Alberta T6G 2H7, Canada). *Eur. J. Pharmacol.* 41(2):183-192; 1977.

Basic pharmacological data on time and dose dependence, site of action, and structure-activity requirements of adenosine were studied to investigate the possible relationship between adenosine-induced relaxation and smooth muscle cyclic AMP levels. Responses to adenosine or to ATP in longitudinal muscle strips of the small intestine of the rabbit were reported to be biphasic, i.e., an initial suppression of contractile activity was followed by a sustained phase of inhibition. Cumulative application of relaxant doses of adenosine or ATP caused less total response than one single application of the cumulative dose. Neither procaine (1 mM), lidocaine (0.17 mM), or guanethidine (10 μM) antagonized the responses to adenosine or to ATP, and the responsiveness of muscles obtained from reserpinized animals appeared unchanged. Histamine, serotonin, and prostaglandin E_1 caused contractile responses. Adenosine derivatives and analogs containing a primary or secondary 6-amino group and unsubstituted 2',3'-hydroxy groups acted as agonists. Those nucleosides (100 μM) found to be inactive plus papaverine (0.1-5 μM), imidazole (10-20 μM), dipyridamole (1 μM), 6-(*p*-nitrobenzyl) thioguanosine, and propranolol (10 μM) did not modify appreciably the responsiveness of the muscle to adenosine or to ATP. Phentolamine (10 μM) and theophylline (10 μM) antagonized adenosine responses. Theophylline (100 μM) produced antagonism (68 ± 5%, N=5) to adenosine at 10 μM concentration; but this inhibitory effect was surmounted at adenosine doses of more than 100 μM. A number of 1,3-alkyl-6-thioxanthines (1-10 μM) caused a slow and small depression of muscle contraction. The results suggest an extracellular receptor site for adenosine and its analogs and the absence of an indirect mechanism of action via nerve stimulation.

4528 EFFECT OF CHOLECYSTOKININ ON MYOELECTRIC ACTIVITY OF SMALL BOWEL OF THE DOG. (Eng.) Mukhopadhyay, A. K.; Thor, P. J.; Copeland, E. M.; Johnson, L. R.; Weisbrodt, N. W. (Univ. Texas Medical Sch., Houston, TX 77030). *Am. J. Physiol.* 232 (1):E44-E47; 1977.

The effect of cholecystokinin on myoelectric activity was determined in the small intestine of conscious dogs. Six animals were implanted with electrodes along the small intestine, and a cannula was placed in the stomach. A second cannula was inserted into the duodenum in three animals, and a pancreatic fistula was prepared in three others. Recordings were made in the fasted state, during the i.v. infusion of either saline or cholecystokinin-octapeptide (CCK-OP, 125 ng/kg/kr), during the intraduodenal infusion of either saline or L-tryptophan (2 or 4 mmol/hr), and during the fed state. CCK-OP disrupted the fasted pattern of myoelectric activity and caused dose-dependent increases in spike potentials and in pancreatic protein secretion. Stimulation of myoelectric activity occurred at doses that produced submaximal protein secretion; however, the stimulation was not identical to that seen with feeding. Intraduodenal infusion of L-tryptophan increased pancreatic protein secretion, interrupted the fasted pattern of motility, and induced a pattern similar to that seen with feeding. It is concluded that CCK alters small intestinal motility and may play a role in the changes in small bowel motility caused by the ingestion of food.

4529 INHIBITORY EFFECT OF METHIONINE- AND LEUCINE-ENKEPHALIN ON CONTRACTIONS OF THE GUINEA-PIG ILEUM ELICITED BY PGE_1. (Eng.) Jaques, R. (Pharmaceuticals Div., CIBA-GIGY Ltd., CH-4002 Basel, Switzerland). *Experientia* 33(3): 374-375; 1977.

The hypothesis that enkephalins antagonize intestinal contractions elicited by prostaglandin E_1 (PGE_1) and that this effect is reversible through the interaction of an opiate antagonist (naloxone) was tested. Low concentrations of methionine-enkephalin (3-30 nM) and leucine-enkephalin (50-100 nM) produced a dose-dependent inhibition of contractions elicited by PGE_1 (0.1 μg/ml) in the isolated guinea pig ileum. Naloxone reversed the inhibitory effects of the enkephalins at concentrations of 650-1,000 mM. These studies show that, like morphine and other narcotic analgesics, enkephalins inhibit the effect of PGE_1 on smooth muscle. This result may implicate prostaglandins in the pathogenesis of pain. The authors suggest that enkephalins or enkephalin-like peptides could occur in the intestine and play a role in regulating gastrointestinal motility.

4530 ACTION OF METHYLXANTHINES AND IMIDAZOLE ON THE CONTRACTILITY OF THE TERMINAL ILEUM OF THE GUINEA PIG. (Eng.) Kazic, T. (Faculty Medicine, Beograd, Yugoslavia). *Eur. J. Pharmacol.* 41(2):103-111; 1977.

The actions of methylxanthines (aminophylline and caffeine) and imidazole on the contractile responses of the terminal ileum were studied to elucidate whether the effects of these substances were attributable to their opposite influences on cyclic nucleotide phosphodiesterase. Aminophylline and caffeine (0.02-24 mM) produced dose-related contractions (5-100% of the maximal contraction) of the terminal ileum that were reduced 79 ± 3% by atropine (1 μg/ml). Physostigmine (0.12 μM) produced two- to threefold potentiation of the contractions produced by aminophylline and caffeine. Hemicholinium (1.75 mM) selectively inhibited (50-70%) the responses to aminophylline and caffeine. The responses to imidazole and noradrenalin were relatively unaffected by atropine, physostigmine, and hemicholinium. Aminophylline (2.2-11 μM) and caffeine (225 μM) were much more efficient in potentiating the responses to electrical stimulation at 30 Hz frequency (train duration 1 sec) than those to electrical stimulation at 3 Hz frequency (train duration 2 sec). Imidazole did not show this type of selectivity and potentiated both types of responses. The potentiation of the nerve-mediated responses by methylxanthines to electrical stimulation was dependent on the external concentration of calcium. Higher concentrations of aminophylline (>0.1 mM) were reported to inhibit histamine- and noradrenalin-induced contractions, presumably due to inhibition of phosphodiesterase in the smooth muscle and subsequent elevation of cyclic AMP levels. It is suggested that the action of imidazole is related to its activating influence on phosphodiesterase in the smooth muscle and that the action of methylxanthines may involve some mechanism other than inhibition of phosphodiesterase.

4531 MODELS OF GASTRIC EMPTYING. (Eng.) Stubbs, D. F. (Anti-Inflammatory Disease Products, Upjohn Co., Kalamazoo, MI 49001). *Gut* 18(3):202-207; 1977.

Some empirical and theoretical models of the emptying behavior of the stomach are presented, and a new model of gastric emptying is derived. Published data on humans were used to test the model and eva uate empirical constants. For meals with an initi volume of ≥300 ml, the reciprocal of the cube root of the volume of meal remaining is proportional to the time the meal is in the stomach. For meals of initial volume of <300 ml, the equation has to be corrected for the fact that the resting volume of gastric contents is about 28 ml. As this model in no neural or hormonal factors, it is suggested tha the gastric emptying response to the volume of a meal does not depend on these factors. The gastri emptying response to the composition of the meal does depend on such factors, and a recent model of this process is used to evaluate an empirical constant.

4532 REEVALUATION OF TRIETHERS AS MARKERS FOR TRIGLYCERIDES DURING GASTRIC EMPTYING. (Eng.) Hoving, J.; Wilson, J. H. P.; Pratt, J. J. Woldring, M. G. (Univ. Hosp., Groningen, Netherlands). *Am. J. Dig. Dis.* 22(5):449-453; 1977.

The validity of using triethers as markers for tri glycerides during gastric emptying was investigate in male Wistar rats and in two humans. The rats received by gastric tube 0.3 ml olive oil containi either 5 μCi ^{131}I-triolein plus 0.5 μCi ^{75}Se-triet or 1.5 μCi ^{14}C-triolein plus 12 μCi ^{3}H-triether. Two duodenal ulcer patients received 18.5 g corn oil, 34.5 g glucose, 31.5 g skimmed milk powder/30 ml water, and 2.1 μCi ^{75}Se-triether dissolved in a mixture of saturated medium-chain triglycerides. The analysis of gastric contents at 0, 15, 60, and 120 min after administration in the rats and at 15 30, and 45 min in the humans showed no evidence of separation of triglyceride and triether in the sto ach. The disappointing results of other workers using ^{3}H-triether may be due to an artifact associated with instability of the tritium-to-triether bond in the preparation used.

SECRETION AND METABOLISM

4544 A PHYSICAL MODEL FOR THE SIMULTANEOUS MEMBRANE TRANSPORT AND METABOLISM OF DRUGS. (Eng.) Ho, N. F. H.; Park, J.; Morozowich, W.; Higuchi, W. I. (Coll. Pharmacy, Univ. Michigan, Ann Arbor, MI). *J. Theor. Biol.* 61(1):185-193; 1976.

A physical model for the intestinal transport of solutes is mathematically described. An aqueous diffusion layer barrier is employed in series with a membrane barrier (a passive diffusional-bioconversion pathway) with an operational aqueous pore pathway in parallel. The model provides the basis for the experimental design of *in situ* studies and for the quantification of physically meaningful and experimentally accessible transport and overall bioconversion kinetic parameters. The interaction and factorization of the following are mathematically explicit: the permeability coefficients of the aqueous diffusion layer, the aqueous pores of the membrane, and the principal membrane transport-bioconversion pathway; the pH and negative logarithm of the equilibrium constant (pKa); and the lipophilicity of the solute. The model is applied to the simultaneous transport and metabolism of prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$) across the jejunal membrane of the rat using an *in situ* non-perfusion technique. The apparent first-order absorption rate constant versus pH profiles at two hydrodynamic situations show the physical interactions between the pH and permeabilities of the aqueous diffusion layer, passive transport-bioconversion pathway, and aqueous pores. Qualitative analyses by high pressure liquid chromatography and thin layer chromatography of the plasma fraction of portal vein blood indicated the presence of 15-keto-$PGF_{2\alpha}$ and 15-keto-13,14-dihydro-$PGF_{2\alpha}$ and the absence of $PGF_{2\alpha}$.

4545 IMMUNOLOGICAL ASPECTS OF SECRETIN, SUBSTANCE P, AND VIP. (Eng.) Yanaihara, N.; Sakagami, M.; Sato, H.; Yamamoto, K.; Hashimoto, T.; Yanaihara, C.; *et al.* (Shizuoka Coll. Pharmacy, 2-2-1 Oshika, Shizuoka, Japan 422). *Gastroenterology* 72(4):803-810; 1977.

Secretin, substance P, and vasoactive intestinal peptide (VIP) were studied immunologically using synthetic hormones and their related peptides. The properties of these hormones were characterized by radioimmunoassays specific to the respective hormones. Antisecretin antisera (NCC-R-1 and R-801) were generated in rabbits with synthetic porcine secretin adsorbed on polyvinylpyrrolidone. Antiserum to substance P (R-400) was produced in a rabbit with synthetic substance P-human α-globulin conjugate. Generation of anti-VIP antiserum (R-502) was carried out by immunizing rabbits with synthetic VIP adsorbed on polyvinylpyrrolidone. Synthetic polypeptides related to the three hormones that were examined included secretin(4-27), secretin-(5-27), secretin(7-27), secretin(11-27), secretin-(14-27), secretin(18-27), secretin(1-22)amide, secretin(7-22)amide, N^{α}-tyrosyl-secretin, [1-Tyr]-secretin, [4-Ala]secretin, [4-D-Ala]secretin, [4-Ala,5-val]secretin, [6-Tyr]secretin, substance P(2-11), substance P(3-11), substance P(4-11), substance P(5-11), substance P(6-11), N^{α}-tyrosyl-substance P, [1-Tyr]substance P, [8-Tyr]substance P, [11-Leu]substance P, des-11-Met-substance P, VIP(7-28), VIP(11-28), VIP(18-28), VIP(1-18)amide, and VIP(1-22)amide. The results revealed two antigenic regions at the amino- and carboxyl-terminal portions of the secretin and VIP molecules. The major antigenic region of substance P was located within the 3 to 11 sequence. The proline residue in position 4 and methionine in position 11 seemed to be of special importance. The immunoassays demonstrated the existence of immunoreactivities of these hormones in hot water extracts from various porcine tissues. In the pituitary, VIP and substance P immunoreactivities were detected, whereas secretin was not. Secretin, VIP, and substance P were found in the pancreas, but at low concentrations. Distributions of these hormones in various sites of the gastrointestinal tract were also demonstrated.

550 EFFECT OF CHANGES IN THE INTRAGASTRIC MILIEU ON COMPETENCE OF THE GASTRO-OESOPHAGAL REGION. A STUDY IN NORMAL SUBJECTS. (Eng.) Besby, S. (Odense Univ. Hosp., DK-5000 Odense, Denmark). *Scand. J. Gastroenterol.* 12(2):215-220; 1977.

Gastroesophageal competence was assessed in 10 healthy subjects during pentagastrin-stimulated acid secretion, during insulin-induced hypoglycemia, and after the intragastric instillation of HCl. The manometrically determined mean basal sphincter pressure was 14 ± 3 mm Hg. No reflux occurred in the basal state; in the basal state when the legs were raised, there was one reflux episode. During pent gastrin infusion (0.015 g/kg, i.v., 15 min), there were eight episodes of reflux in six subjects, but this was not statistically significant. There wer no significant differences in intragastric pressur during leg raising before or after pentagastrin infusion. Although 60 min following the i.v. inje tion of insulin (0.2 IU/kg) the intragastric pH wa reduced from a mean 1.6 to a mean 1.1 ($p<0.01$), hypoglycemia and increased intragastric acidity ha no significant effect on gastroesophageal competen or sphincter pressure, either while the subject wa at rest or during leg raising. The intragastric instillation of 0.1 N HCl (200 ml) reduced the int gastric pH from 1.6 to 1.1 and resulted in 26 episodes of reflux in seven subjects ($p<0.02$). There was no significant change in intragastric pressure on leg raising during the instillation of HCl. The results demonstrate that in normal subjects only the increased gastric acidity resulting from HCl instillation causes a weakening of the gastroesophageal region.

4551 EFFECT OF LONG-TERM PARENTERAL FEEDING ON GASTRIC SECRETION IN DOGS. (Eng.) Thor, P. J.; Copeland, E. M.; Dudrick, S. J.; Johnson, L. R. (Univ. Texas Medical Sch., Houston, TX 77030). *Am. J. Physiol.* 232(1):E39-E43; 1977.

Total parenteral nutrition was used to study the effects of food on gastric secretion and serum gastrin levels. Three dogs were surgically prepared with gastric fistulas and Heidenhain (vagally denervated) pouches. Acid and pepsin responses to pentagastrin and food were determined before and at the end of a 1-month period of total parenteral feeding, and 1 month after resumption of a normal p.o. diet. Acid and pepsin output from the denervated pouch in response to pentagastrin and food decreased significantly ($p<0.001$) after parenteral feeding and returned to control levels after the dogs resumed a normal diet. Secretory outputs from the gastric fistula in response to pentagastrin remained unchanged. Basal serum gastrin levels decreased 50% during the period of i.v. feeding and returned to levels approximately twice control levels following resumption of normal food intake. Serum gastrin responses to a meal also decreased during parenteral nutrition and returned to higher than normal levels following a 1-month period of p.o. intake. These studies indicate that the absence of p.o. food intake in the dog does not result in decreased acid secretion from the innervated stomach. Vagal innervation in some way is responsible for the preservation of normal secretion during the absence of food from the gastrointestinal tract.

4552 STEREOLOGICAL ANALYSIS OF THE PARIETAL CELL DURING ACID SECRETION AND INHIBITION. (Eng.) Zalewsky, C. A.; Moody, F. G. (Univ. Utah Medical Center, 50 North Medical Drive, Salt Lake City, UT 84132). *Gastroenterology* 73(1):66-74; 1977.

A stereological membrane analysis was carried out to quantitate the ultrastructural changes of canine parietal cells of the fundic gastric mucosa during inhibition of histamine-activated acid secretion by cimetidine (3 mg/kg/hr), isoproterenol (1 μg/kg/min), and thiocyanate (0.2 mEq/min). Surface density (S_V) of secretory, tubulovesicular, and nutrient membranes was quantitated by stereological methods. Of 118 parietal cells taken from resting mucosa, 5.7% appeared secreting and 13.6% of 165 histamine-stimulated cells retained their resting configuration. With histamine (1 μg/kg/min), secretory membrane increased and tubulovesicular membrane was reduced. Except for thiocyanate-inhibited cells, a linear relationship existed between secretory membrane S_V and acid output. Complete-inhibition of histamine-stimulated acid secretion was produced by cimetidine in 30-45 min, isoproterenol in 1.5-4 hr, and thiocyanate in 1.25 hr. Based on their ultrastructural response, a total of 88.6% of cimetidine-inhibited cells returned to resting in comparison to 51.1% of isoproterenol-inhibited cells and 26.4% of thiocyanate-inhibited cells. Thus, after treatment by cimetidine, secreting cells returned most quickly and completely to their resting ultrastructural state. Isoproterenol was a slower-acting inhibitor with an ultrastructural effect intermediate between those of cimetidine and thiocyanate. Both cimetidine and isoproterenol decreased secretory membrane S_V during acid inhibition. In contrast, thiocyanate-inhibited parietal cells showed no statistical decrease in S_V, although lumenal acid secretion ceased.

4553 INCREASED SERUM GASTRIN CONCENTRATIONS AND GASTRIC ACID HYPOSECRETION IN THE IMMEDIATE NEWBORN PERIOD. (Eng.) Euler, A. R.; Byrne, W. J.; Cousins, L. M.; Ament, M. E.; Leake, R. D.; Walsh, J. H. (Univ. California at Los Angeles Sch. Medicine, Los Angeles, CA 90024). *Gastroenterology* 72(6):1271-1273; 1977.

Thirty-two infants and their mothers were studied to determine the source of elevated serum gastrin concentrations in umbilical blood and to learn whether neonates hypersecrete acid in response to hypergastrinemia. The mean maternal gastrin level at delivery was significantly higher (mean, 67 pg/ml) than in 809 normal adults (mean, 49 pg/ml, $p<0.001$) and in levels postpartum (mean, 50 pg/ml, $p<0.001$). The serum gastrin levels in the umbilical artery (mean, 105 pg/ml) and vein (mean, 107 pg/ml) were similar ($p>0.5$), but were significantly higher than maternal delivery samples ($p<0.001$). The umbilical artery and vein values were significantly higher than infant values at 4 hr (mean, 76 pg/ml; $p<0.001$, $p<0.005$) and 8 hr (mean, 74 pg/ml; $p<0.025$, $p<0.05$). No significant amount of gastrin was measured in placental extracts. These results suggest that the increased neonatal gastrin concentrations were fetal in origin. Continuous basal acid secretory studies done for 4 hr in 32 infants and for 8 hr in 9 infants demonstrated gastric acid hyposecretion for the first 5 hr of life ($p<0.001$). Acid secretion during hours 6-8 was similar to that in 14 older children ($p>0.5$). Increased gastrin levels were still present at hour 8 and were associated with normal gastric acid secretion.

4554 STIMULATION OF GASTRIN SECRETION AND SYNTHESIS IN ANTRAL ORGAN CULTURE. (Eng.) Harty, R. F.; van der Vijver, J. C.; McGuigan, J. E. (Univ. Florida Coll. Medicine, Gainesville, FL 32610). *J. Clin. Invest.* 60(1):51-60; 1977.

Stimulation of gastrin release and the synthesis of gastrin were examined directly by measuring the incorporation of ^{3}H-tryptophan into gastrin in rat antral mucosal explants maintained in organ culture. Gastrin synthesis and secretion were assessed simultaneously at intervals during explant culture. Antral mucosal explants from fed female Wistar rats were cultured at 37 C (95% O_2/5% CO_2) in medium containing 70% Trowell-T8 and 10% NCTC-135 without tryptophan, 10% dialyzed fetal calf serum, and ^3H-tryptophan (100 μCi/ml). Incorporation of ^3H-tryptophan into immunoreactive gastrin was determined by double-antibody immunoprecipitation. Antral tissue protein synthesis was assessed by ^3H-tryptophan incorporation into tissue protein of the cultured explants. In paired experiments, gastrin synthesis and secretion in the presence of dibutyryl cyclic AMP (DBCAMP) were compared to those in control conditions. Gastrin and protein specific activity increased progressively with time. Gastrin specific activity at 30 min increased from 3.3 ± 0.5 to 55.2 ± 10.6 fmol ^3H-tryptophan/pmol gastrin at 24 hr; specific activity of antral tissue protein at 30 min increased from 33.6 ± 8.4 to 1,660 ± 236 fmol ^3H-tryptophan/μg protein at 16 hr. Culturing explants for 4 hr in the presence of cycloheximide (100 μg/ml) inhibited gastrin and protein synthesis by >90% and 95%, resp. DBCAMP (10 mM) significantly increased the synthesis and secretion of antral gastrin compared with control cultured explants. The results provide a direct demonstration of gastrin synthesis by rat antral mucosal explants in organ culture, indicate that both gastrin and total antral protein synthesis are inhibited by cycloheximide, and demonstrate DBCAMP-induced stimulation of gastrin synthesis and secretion, suggesting the potentially important role of cyclic AMP in gastrin cell function.

4555 MEDIATION OF GUINEA PIG GASTRIN SECRETION IN VITRO BY CYCLIC NUCLEOTIDES. (Eng.)

Schebalin, M.; Zfass, A. M.; Makhlouf, G. M. (Medical Coll. Virginia, Richmond, VA 23298). *Gastroenterology* 73(1):79-83; 1977.

To determine whether cyclic nucleotides are mediators in gastrin secretion, the effect of methacholine, theophylline, and cyclic adenyl and guanyl nucleotides on gastrin secretion from antral and proximal duodenal mucosa of the guinea pig was studied. Both 2 mM dibutyryl (DB) cyclic AMP and 5 mM theophylline produced significant increases in gastrin secretion, 4.3 ± 0.7 ($p<0.001$) and 9.3 ± 2.4 pg/mg/min ($p<0.005$), resp., above basal gastrin secretion (1.5 ± 0.4 pg/mg/min). The combined effect of the two agents was additive (14.5 ± 3.6 pg/mg/min). DB cyclic GMP (2 mM) had no effect on gastrin secretion. Methacholine produced a dose-related increase in gastrin secretion that, at maximum, equaled the combined effect of theophylline and DB cyclic AMP. The results suggest that gastrin secretion is mediated in part by intracellular cyclic AMP but do not exclude a cooperative involvement of cyclic GMP.

4556 NEITHER CYCLIC AMP NOR CYCLIC GMP APPEAR TO MEDIATE ANTRAL GASTRIN RELEASE IN THE DOG. (Eng.)

Krejs, G. J.; Sauberli, H. A.; Largiader, F.; Walsh, J. H.; Blum, A. L. (Univ. Texas Health Science Center at Dallas, Southwestern Medical Sch., Dallas, TX). *Acta Hepatogastroenterol.* 24(2):106-109; 1977.

In vivo experiments were carried out in dogs to evaluate whether cyclic nucleotides act as mediato in antral gastrin release. An antral pouch was constructed, and the rest of the stomach, along with the pancreas, and small and large intestines were resected. A gastric artery supplying the pouch was cannulated and, after a basal period with saline infusion, either dibutyryl cyclic 3',5'-adenosine monophosphate (cyclic AMP, 0.2 mg/kg/min), dibutyryl cyclic 3',5'-guanosine monophosphate (cyclic GMP, 0.05 mg/kg/min), or saline were infused over a period of 60 min. To prove the viability of the pouch and to show its ability to release gastrin with proper stimulation, bethan chol chloride (urecholine) was infused into the gastric artery at the end of the experiment. Bloo samples were taken from the portal vein and assayed for gastrin. Neither cyclic AMP nor cycli GMP infusion increased portal gastrin concentration significantly. A marked increase in portal gastrin concentration, however, was observed when bethanechol chloride was infused. These studies do not support the thesis that cyclic nucleotides mediate gastrin release in the dog.

4557 INFLUENCE OF AMYTAL AND MENADIONE ON HIG ENERGY PHOSPHATES AND ACID SECRETION IN FROG GASTRIC MUCOSA. (Eng.)

Hersey, S. J. (Dept. Physiology, Emory Univ., Atlanta, GA 30322). *Biochim. Biophys. Acta* 496(2):359-366; 1977.

The influence of amytal and menadione on cellular energy levels was studied in isolated bullfrog gastric mucosa to further examine the apparently specific action of amytal on acid production. The mucosa was mounted in a double chamber to provide paired segments from the same animal, and acid secretion was measured by the pH stat method. In the first series of experiments, one member of the tissue pair was treated with 8 mM amytal, while the other member served as control. Amytal treatment resulted in a 25% decrease in ATP levels ($p<0.01$) and in a decrease in creatine phosphate from a control level of 31.9 nmol/mg to 8.3 nmol/mg ($p<0.01$). In the second series of experiments, both members of the tissue pair were treated with amytal and one member was subsequently given menadione plus ascorbate. The menadione/ascorbate was added at a time when the secretory rate had reached approximately 50% of its initial value so as to permit exposure of the tissue to menadione/ascorbate for a minimum of 30 min prior to freezin Tissues treated with menadione/ascorbate showed significantly greater ATP content (20.6 nmol/mg) and creatine phosphate levels (19.9 nmol/mg) than tissues treated with amytal alone (16.6 and 12.1 nmol/mg, resp., $p<0.01$ in both cases). Net chlori transport was measured as the difference between the short-circuit current and the rate of hydrogen ion secretion. Amytal resulted in inhibition of both short-circuit current and hydrogen ion secretion; chloride transport was thus inhibited by amytal. Chloride transport was partially restored by menadione/ascorbate to the point where inhibition of chloride transport equalled that of hydroge ion secretion. These results indicate that menadione/ascorbate can support the output of nonacidic chloride but not that of chloride associated with acid. It is concluded that an amytal-sensitive reaction, presumably at mitochondrial coupling site I, is required for acid secretion to occur and that ATP is not a sufficient source of energy for this secretory process.

4558 RAT GASTRIC MUCOSAL ADENYLYL CYCLASE. (Eng.) Thompson, W. J.; Chang, L. K.; Jacobson, E. D. (Univ. Texas Medical Sch., Houston, TX 77030). *Gastroenterology* 72(2):244-250; 1977.

The ability of various activators and inhibitors of gastric secretion to stimulate adenylyl cyclase activity in the *in vitro* rat stomach was studied to test the hypothesis that increased intracellular cyclic AMP is necessary for the stimulation of gastric acid secretion by secretagogues. The 600 x *g* membrane adenylyl cyclase activity was maximally stimulated by 5 mM NaF and by 5'-guanylylimidodiphosphate, but not by guanosine-5'-triphosphate (50 μM). The acid secretory inhibitors prostaglandin E_1 (100 μM), epinephrine (50 μM), secretin (0.2 μM), and glucagon (20 μM) all stimulated mucosal membrane adenylyl cyclase activity from the stomach corpus. The gastric acid secretagogues pentagastrin (20 μM), histamine (1 mM), or carbachol (1 mM) had no effect on basal or prostaglandin E_1-stimulated adenylyl cyclase activity. The enzyme exhibited Michaelis-Menten kinetics with respect to the concentration of ATP, having an apparent Km of 0.25 mM. Histamine did not stimulate rat mucosal adenylyl cyclase activity under a variety of experimental conditions (i.e., tissue from fed and fasted animals, different homogenization media, use of whole homogenate versus different cell fractions, and *in vitro* additives with histamine); however, it did stimulate the same enzyme in guinea pig gastric fundic mucosa, an enzyme also activated by prostaglandin E_1. These studies do not support the hypothesis that cyclic AMP mediates the actions of gastric acid secretagogues on the parietal cell in the rat.

4559 ROLE OF ENDOGENEOUS CALCITONIN IN THE SECRETION OF GASTRIN AND GASTRIC ACID IN RATS. (Eng.) Ito, H.; Sakurada, T.; Orimo, H. (Tokyo Metropolitan Geriatric Hosp., 35-2 Sakae-cho, Itabashi-ku, Tokyo, Japan). *Horm. Metab. Res.* 9(1):89-92; 1977.

The physiological role of calcitonin on gastric acid secretion and on serum gastrin was studied in male Wistar rats. The accumulation of gastric acid in pylorus-ligated animals with or without thyroidectomy (76 ± 3 and 44 ± 4 μEq/2 hr, resp.) was significantly greater than in nonligated controls (28 ± 5 μEq/2 hr, $p<0.001$). The accumulation of gastric acid following the pyloric ligation was significantly greater in the thyroidectomized rats than in the thyroid intact rats ($p<0.001$). Serum immunoreactive gastrin levels in the pylorus ligated rats with thyroidectomy (132 ± 14 pg/ml) and without thyroidectomy (85 ± 8 pg/ml) were significantly greater than in the nonligated animals (45 ± 7 pg/ml, $p<0.01$). Serum calcium levels were not significantly different in the three groups. Eight animals underwent parathyroid autotransplantation to the femoral muscle; 2 weeks later, they were sham-operated or thyroidectomized. Both groups were given glycine (50 mg/100 g) as a 10% solution by stomach tube. Serum immunoreactive gastrin levels increased significantly at 30 and 60 min after glycine administration, and this level was significantly higher in the thyroidectomized rats at 30 min ($p<0.02$) and 60 min ($p<0.05$). In eight similarly treated animals that received rat chow homogenate instead of glycine through the stomach tube, serum immunoreactive gastrin levels at 30 min after the ingestion of rat chow was significantly higher in the thyroidectomized animals. The results suggest that endogenous calcitonin has an inhibitory action on gastric acid secretion, probably through the inhibitory action on gastrin secretion in rats.

4560 GASTRIC AND EXTRAGASTRIC GASTRIN RELEASE IN NORMAL SUBJECTS, IN DUODENAL ULCER PATIENTS, AND IN PATIENTS WITH PARTIAL GASTRECTOMY (BILLROTH I). Fritsch, W. P.; Hausamen, T. U.; Rick, W. (I. Medizinische Klinik A, Universitat Dusseldorf, W. Germany). *Gastroenterology* 71(4): 552-557; 1976.

Gastrin release after p.o. and intraduodenal stimulation (test meal) was examined in 10 normal subjects, 32 patients with duodenal ulcer, and 11 patients with gastroduodenostomy (Billroth I) without vagotomy. In addition, the effect of extragastric gastrin on gastric acid secretion was investigated. The mean serum gastrin levels rose from fasting levels of 43, 72, and 38 pg/ml in the normal, duodenal ulcer, and gastroduodenostomy patients to peak concentrations of 110, 201, and 61 pg/ml ($p<0.0025$, 0.005, and 0.05), resp., after the oral test meal. These levels also rose significantly after an intraduodenal test meal from basal levels of 49, 61, and 33 pg/ml in the normal, duodenal ulcer, and gastroduodenostomy patients, resp., to 77, 117, and 64 pg/ml. After the intraduodenal test meal an increase in gastric acid secretion and serum gastrin was observed in four normal subjects and 17 duodenal ulcer patients. In the basal state, after an intraduodenal or p.o. test meal, duodenal ulcer patients with normal gastric acid secretory capacity had higher serum gastrin concentrations than duodenal ulcer patients with gastric hypersecretion. There was a good correlation between peak serum gastrin levels after the p.o. and after the intraduodenal meals. It is concluded that: (a) intraduodenal application of a test meal results in release of gastrin from extragastric sites; (b) extragastric gastrin is biologically active, and (c) duodenal ulcer patients are able to release more antral and more extragastric gastrin in response to a test meal.

4561 ON THE SYNTHESIS OF PROSTAGLANDINS BY HUMAN GASTRIC MUCOSA AND ITS MODIFICATION BY DRUGS. (Eng.) Peskar, B. M. (Medizinische Klinik, Univ. Freiburg, D-78 Freiburg i.Br., W. Germany). *Biochim. Biophys. Acta* 487(2):307-314; 1977.

Specific radioimmunoassays for prostaglandins E_2, A_2, and $F_{2\alpha}$ were used to study the synthesis of prostaglandins by gastroscopically obtained small biopsy specimens of human gastric corpus mucosa. Both prostaglandin E_2 and prostaglandin $F_{2\alpha}$ were found to be synthesized from arachidonic acid by the microsomal fraction of human gastric mucosa. The synthesis of prostaglandin E_2 exceeded that of prostaglandin $F_{2\alpha}$ by a factor of about 10. Prostaglandin A_2 or B_2 synthesis was not observed under the same incubation conditions. Indomethacin effectively inhibited synthesis of both prostaglandin E_2 (ID_{50}, 4.2 μg/ml) and prostaglandin $F_{2\alpha}$ (ID_{50}, 1.8 μg/ml) by human gastric mucosa, while paracetamol even in a concentration of 310 μg/ml did not influence prostaglandin synthesis. Carbenoxolone at the same concentration only inhibited prostaglandin synthesis by about 20%. The results support the hypothesis that the gastrointestinal effects or side-effects of several drugs are mediated by an influence on the enzymes of prostaglandin synthesis or inactivation.

4562 INFLUENCE OF THE ROUTE OF ADMINISTRATION OF PROSTAGLANDIN E_1 ON RAT GASTRIC SECRETION.

(Eng.) Hong, E.; Lopez, C. (Instituto Miles de Terapeutica Experimental, Calzada Xochimilco 77, Mexico 22, D.F., Mexico). *Prostaglandins* 13(4):691-696; 1977.

The effects of subcutaneous, intraduodenal, and intragastric administration of prostaglandin E_1 (PGE_1) upon gastric secretion in pylorus-ligated rats were compared. Male Wistar rats were fasted for 48 hr prior to the experiment, pylorus ligation was performed, and PGE_1 was administered immediately. Gastric secretion was measured 4 hr later. Subcutaneous injection of PGE_1 produced dose-related decreases in gastric acid secretion and volume that were greater than, but parallel to, those produced by intraduodenal administration of PGE_1. The ED_{50}'s for inhibiting acid secretion and volume by s.c. administration were 1.3 and 1.6 mg/kg, while the ED_{50}'s for inhibition by intraduodenal administration were 19.0 and 20.9 mg/kg, resp. Intragastric administration resulted in a dose-related increase in volume (ED_{50}=22.2 mg/kg) and a dose-related decrease in acid (ED_{50}=14.8 mg/kg). The dose-response curve for intragastric administration had a slope of only 7.2 while the slopes observed with s.c. and intraduodenal administration were 26.9 and 23.8, resp. The authors propose that PGE_1 may be less effective when administered intraduodenally than when administered s.c. due to a greater metabolism of PGE_1 during absorption from the intestines or to a less efficient absorptive process from the duodenum. The increase in volume after intragastric administration might be explained by an increased blood flow from the capillaries, possibly due to localized inflammation. PGE_1 administered intragastrically may also act directly on the oxyntic cells to decrease acid secretion.

4563 GASTRIC ANTISECRETORY EFFECTS OF E PROSTAGLANDINS IN RHESUS MONKEYS.

(Eng.) Dajani, E. Z.; Callison, D. A.; Bianchi, R. G.; Driskill, D. R. (Dept. Biological Res., Searle Lab., Box 5110, Chicago, IL 60680). *Am. J. Dig. Dis.* 21(12):1020-1028; 1976.

Prostaglandin E_1 methyl ester (PGE_1ME) and E_2 (PGE_2 were tested for antagonistic action on histamine an pentagastrin-stimulated gastric secretion in female rhesus monkeys (*Macaca mulatta).* Histamine (0.1 mg kg) or pentagastrin (15 μg/kg) was injected s.c. in conscious monkeys at four 1-hr intervals to stimulate secretion to 69% or 100% of the predetermined maximal response, resp. When a plateau was reached the prostaglandins (10-100 μg/kg) were injected i.v in a single bolus. Gastric secretion was aspirated at 0.5-hr intervals and analyzed for volume, acid content, and ion concentrations. PGE_1ME inhibited basal and histamine/pentagastrin-stimulated gastric secretion, and PGE_2 inhibited histamine-stimulated gastric secretion. Gastric acid concentration was inhibited ($p<0.05$) for at least 1 hr with doses of 10 μg/kg PGE_1ME and 30 μg/kg PGE_2. The volume of histamine-stimulated gastric fluid secretion was significantly depressed ($p<0.05$) only by 100-μg/kg doses of either prostaglandin. Both reduced hydrogen ion output and increased gastric sodium ion concentrations, but chloride and potassium ion concentrations were not altered. The gastric secretor responses of the rhesus monkey appear to be similar to those of man, and the monkeys lacked the severe side effects seen in other animals in response to prostaglandins. The rhesus monkey is concluded to be an adequate species for studying the gastric anti-secretory effects of prostaglandins.

4564 THE EFFECT OF THE SYNTHETIC PROSTAGLANDI ANALOG 15 (R) 15 METHYL-PGE_2 METHYL ESTE ON GASTRIC MUCOSAL HEMORRHAGE INDUCED IN RATS BY TAUROCHOLIC ACID AND HYDROCHLORIC ACID.

(Eng.) Carmichael, H. A.; Nelson, L.; Russell, R. I.; Lyon, A.; Chandra, V. (Royal Infirmary, Glasgow G4 OSF, Scotland). *Am. J. Dig. Dis.* 22(5):411-414; 1977.

The incidence of mucosal hemorrhage induced in Sprague-Dawley rats by the p.o. administration of taurocholic acid (TCA) and hydrochloric acid (HCl), both singly and in combination, was investigated. The effect of prostaglandin 15 (R) 15 methyl-PGE_2 methyl ester (Me-PGE_2) on the occurrence of hemorrhage induced by TCA with HCl was also studied. The incidence of hemorrhage induced by TCA (10 mM) alone and HCl (160 mM) alone was minimal and simila to that induced by the control solution. The combination of TCA (10 mM) and HCl (160 mM) produced bleeding in 67.7% of animals. The addition of Me-PGE_2 (9.9 μM, corresponding to 50 μg/kg) significantly reduced the incidence of hemorrhage induced by the combination of TCA with HCl from 67.7% to 31.3%. This result suggests that this synthetic prostaglandin may be of value in conditions thought to be associated with reflux of bile into the stomach.

4565 THE POSSIBLE MECHANISM FOR THE 'FADE' IN ACID GASTRIC SECRETION DURING CONTINUOUS INFUSIONS OF PENTAGASTRIN.

(Eng.) Sanyal, A. K.;

Waton, N. G. (Dept. Physiology and Pharmacology, Univ. Strathclyde, Glasgow, G1 1XW, Scotland). *J. Physiol.* 261(2):445-451; 1976.

The "fade" phenomenon seen in acid gastric secretion in response to a continuous i.v. infusion of pentagastrin was studied in eight anaesthetized cats in 3-hr infusion experiments. The results were expressed as percentage of the total 3-hr secretion observed at the 15-min sampling intervals. Continuous infusion of histamine produced a steady increase in acid secretion up to a maximum at 3 hr (11.5 ± 1.0%). However, pentagastrin infusion led to a steep rise in acid secretion to a maximum at 45 min (12.1 ± 1.5%) and then gradually decreased for 2 hr to reach about 60% (6.2 ± 0.6%) of the maximum. Pretreatment of the cats with drugs that block or deplete 5-hydroxytryptamine (5-HT) methysergide (1.0 mg/kg), cyproheptadine (0.4 mg/kg), or reserpine (0.1 mg/kg), resulted in an acid secretion response to pentagastrin similar to that seen during infusion of histamine. These drugs did not affect secretion stimulated by histamine. The results suggest that the "fade" phenomenon is due to a release of 5-HT from the tissues stimulated by pentagastrin. It is suggested that 5-HT first potentiates and then inhibits the resulting stimulated secretion.

4566 MUCINOUS SECRETION FROM CANINE HEIDENHAIN POUCH AFTER STIMULATION WITH FOOD, PENTAGASTRIN AND HISTAMINE.

(Eng.) Kowalewski, K.; Pachkowski, T.; Secord, D. C. (Surgical-Medical Res. Inst., Univ. Alberta, Edmonton, Alberta T6G 2N8, Canada). *Eur. Surg. Res.* 8(6):536-544; 1976.

Principal glycoproteins and amino acids were determined in the gastric juice obtained from Heidenhain pouches of dogs after stimulation with food, histamine (1 mg/kg, at 0, 2, and 4 hr of the 6-hr collection period), or pentagastrin (6 μg/kg, at hr 0, 2, and 4). All stimulants induced voluminous secretion, and histamine was the best stimulant. In both the fasting secretion and in the three types of stimulated secretion, the galactose to glucosamine ratio was close to 1:1, and the galactose to galactosamine ratio approached 2:1. The concentrations of all carbohydrate components (i.e., galactose, glucosamine, galactosamine, fucose, and mannose) with the exception of glucose were higher in nonstimulated fasting secretions than in stimulated secretions ($p<0.01$). The concentrations of galactose, glucosamine, galactosamine, glucose, and fucose were found in significantly lower concentrations in histamine-stimulated secretions than in secretions obtained after feeding ($p<0.05$) or pentagastrin ($p<0.05$). Proline, leucine, glutamic acid, and aspartic acid were the principal amino acids in all four groups of gastric juice hydrolysates. The threonine to serine ratios were close to 1:1, and threonine and serine contributed only 11-20% of the amino acids. Threonine, serine, proline, alanine, and glycine accounted for 35-40% of the total amino acids. These results differ considerably from the relative concentrations of amino acids and carbohydrates found in human gastric juice, but this may be due to species differences.

4567 EFFECT OF HISTAMINE ON CANINE GASTRIC MUCOSAL ADENYLATE CYCLASE.

(Eng.) Dozois, R. R.; Wollin, A.; Rettmann, R. D.; Dousa, T. P. (Mayo Clinic, Rochester, MN 55901). *Am. J. Physiol.* 232(1):E35-E38; 1977.

Evidence that histamine stimulates the adenylate cyclase of isolated gastric mucosal preparations was sought to fill in the missing link in the sequence of associations of cyclic AMP with HCl secretion. The effects of histamine, N^{α}-dimethylhistamine, 4,5-methylhistamine, N^{τ}-methylhistamine, pentagastrin, carbachol, and NaF on the adenylate cyclase activity from canine gastric mucosa were investigated in cell-free preparations. In gastric fundic mucosa, histamine (10^{-4} M), N^{α}-dimethylhistamine (10^{-4} M), 4,5-methylhistamine (10^{-4}M), and NaF (10^{-2} M) significantly ($p<0.001$) increased adenylate cyclase activity by 44.7% ± 6.6%, 49.4% ± 6.7%, 34.0% ± 6.4%, and 572.0% ± 100%, resp., above basal activity. The effect of histamine and Nα-dimethylhistamine was dose-dependent. In contrast, other tested agents failed to stimulate the formation of cyclic AMP in gastric fundic mucosa. Metiamide (10^{-4} M) blocked the stimulation of fundic mucosa adenylate cyclase by histamine and Nα-dimethylhistamine without significantly altering basal and NaF-induced adenylate cyclase activity. Histamine, however, did not stimulate the adenylate cyclase activity from the gastric antral mucosa. The canine gastric acid response to histamine may be mediated by cyclic AMP formed in response to stimulation of histamine H_2-receptors.

4568 HYPEROSMOTIC OXIDATION OF GLUCOSE AND DECARBOXYLATION OF HISTIDINE IN THE GASTRIC MUCOSA.

(Eng.) Sernka, T. J.; Jackson, A. F. (Wright State Univ. Sch. Medicine, P. O. Box 927, Dayton, OH 45401). *Physiol. Chem. Phys.* 8(4):309-317; 1976.

The metabolic effects of the physiological reactions of the gastric mucosa to hyperosmotic agents were studied. Paired slices of rat gastric mucosa were incubated with labeled glucose or histidine in isosmotic solution or threefold hyperosmotic solutions concentrated in NaCl, KCl, or ethanol. The rate of $(1-^{14}C)$-glucose oxidation to $^{14}CO_2$ in isosmotic solution was reduced by 74% in hyperosmotic NaCl and by 28% in hyperosmotic KCl. The rate of $(6-^{14}C)$-glucose oxidation to $^{14}CO_2$ in isosmotic solution was reduced by 64% in hyperosmotic NaCl and by 53% in hyperosmotic KCl. Reductions of glucose oxidation in hyperosmotic ethanol were not significant. The ratio of $^{14}CO_2$ formed from $(1-^{14}C)$-glucose to that formed from $(6-^{14}C)$-glucose was not significantly changed by hyperosmotic NaCl or ethanol, but was significantly raised by hyperosmotic KCl. The rate of (carboxyl-^{14}C)-histidine decarboxylation in isosmotic solution was reduced significantly by 48% in hyperosmotic NaCl, by 30% in hyperosmotic KCl, and by 27% in hyperosmotic ethanol. It is concluded that hyperosmotic solutions reduce glucose oxidation and histidine decarboxylation by rat gastric mucosa in the order of potency: NaCl>KCl>ethanol. Thus hyperosmotic solutions inhibit the source of metabolic energy for stimulated acid secretion, the citric acid cycle, and the formation of the secretagogue histamine.

4569 EFFECT OF GRADED MECHANICAL ISCHEMIA ON OXYGEN TENSION AND ELECTRICAL POTENTIAL IN THE CANINE GASTRIC MUCOSA: A NEW EXPERIMENTAL MODEL. (Eng.) Bowen, J. C.; Garg, D. K. (Ochsner Clinic, 1514 Jefferson Highway, New Orleans, LA 70121). *Gastroenterology* 73(1):84-88; 1977.

The applicability of an ultramicroelectrode technique to the study of the gastric mucosa was tested, and the effect of change in total gastric blood flow on mucosal oxygen tension (PO_2) and membrane potential difference (PD) was studied using this technique. Oxygen tension and PD were measured in the gastric mucosa of anesthetized dogs while total blood flow and arteriovenous oxygen content difference were measured. In the control period, measurements were: gastric blood flow, 102.4 ± 3.0 ml/min/100 g tissue; calculated oxygen consumption, 2.4 ± 0.1 ml/min/100 g tissue; intracellular oxygen tension, 15.0 ± 0.6 mm Hg; and intracellular PD, -50.8 ± 1.5 mV. When gastric blood flow was reduced 50% by tourniquet ischemia, oxygen tension decreased 20% ($p<0.05$), but electrical potential and oxygen consumption did not change. When blood flow was reduced 75%, oxygen tension and PD decreased significantly (60% and 35%, resp.), but oxygen consumption was unchanged. Zero blood flow reduced oxygen tension, electrical potential, and total oxygen consumption to zero; release of the arterial tourniquet allowed them to return to control levels. The critical oxygen tension at which the electromotive force generated by the gastric mucosal cells was reduced averaged 9 mm Hg. This result suggests that safety factors exist in the gastric circulation that permit a 60% reduction in total gastric blood flow to occur before an insufficiency of intracellular oxygen begins to limit cellular metabolism within the mucosa.

4570 ION SELECTIVE EFFECTS OF SALICYLATE ON ANTRAL MUCOSA. (Eng.) Fromm, D. (Harvard Medical Sch., Boston, MA). *Gastroenterology* 71(5):743-749; 1976.

The effects of luminal salicylate (5 mM) on rates of ion transport were investigated in isolated rabbit antral mucosa. At neutral luminal pH, salicylate increased Na permeability (mucosa to serosa, Δ 1.1 ± 0.2 $\mu Eq/hr/cm^2$, $p<0.001$; serosa to mucosa, Δ 0.9 ± 0.1 $\mu Eq/hr/cm^2$, $p<0.001$) and decreased Cl permeability (mucosa to serosa, Δ -1.1 ± 0.4 $\mu Eq/hr/cm^2$, $p<0.01$; serosa to mucosa, Δ -3.6 ± 0.4 $\mu Eq/hr/cm^2$, $p<0.001$). Salicylate did not alter net Na transport significantly but decreased the net Cl secretion (2.4 ± 0.3 $\mu Eq/hr/cm^2$). At luminal pH 4, the effects of salicylate were arbitrarily divided into two phases. The initial phase was associated with an increase in Na and marked decrease in Cl permeability. Subsequently, a greater increase in Na permeability and a marked increase in Cl permeability occurred. Active Na transport persisted in the presence of salicylate at pH 4. Indirect evidence also suggested that Cl secretion persisted
under these conditions, but at a reduced rate. Th
rate of luminal acid loss also increased in the
presence of salicylate. A fourfold increase in sa
icylate concentration or a decrease in luminal pH
from 4 to 3 did not appear to intensify the effect
observed for 5 mM salicylate at pH 4. The increas
in cation and decrease in anion permeability obser
at neutral pH and initially at pH 4 are compatible
with an influence of the negative charge of the
salicylate anion. The subsequent changes observed
in the presence of acid also are compatible with t
concept that as the mucosa becomes overwhelmed wit
acid, a nonspecific increase in permeability occur
However, the effect of salicylate on active Cl tra
port is largely independent of acid diffusing into
the mucosa.

4571 ENDOGENOUS SEROTONIN IN THE CONTROL OF GASTRIC ACID SECRETION. (Eng.) Jaffe, B. M.; Kopen, D. F.; Lazan, D. W. (Dept. Surgery, Washington Univ., 4960 Audubon Ave., St. Louis, MO 63110). *Surgery* 82(1):156-163; 1977.

The possible role of serotonin in the duodenal con
trol of gastric acid secretion was evaluated by
comparing the ability of endogenous and exogenous
serotonin to inhibit gastric secretion and escape
hepatic inactivation. In three dogs with Heidenhain pouches (HP), gastric fistulas (GF), and
duodenal cannulas, acidification of the duodenum
with 0.1 N HCl (5 ml/min) resulted in significant
inhibition of GF output (preacidification, 8.66
± 0.58 mEq/30 min; postacidification, 5.47 ± 0.66
mEq/30 min) and elevated peripheral venous blood
levels of serotonin (basal, 226 ± 64 ng/ml; peak,
521 ± 168 ng/ml). Infusion of exogenous serotonin
to comparable blood levels (basal, 208 ± 38 ng/ml;
mean postacidification, 571 ± 153 ng/ml) resulted
in similar GF inhibition (preacidification, 9.17 ±
0.92 mEq/30 min; postacidification, 6.49 ± 0.56 mE
30 min). Per 1 ng/ml increment in peripheral bloo
serotonin, endogenous serotonin inhibited 54.59 ±
12.99 $\mu Eq/hr$ and exogenous serotonin inhibited 46.
± 10.39 $\mu Eq/hr$, ($p<0.05$). Neither endogenously
released nor exogenous serotonin inhibited HP acid
output. Using mesenteric venous infusions of
serotonin, significant amounts of immunoreactive
serotonin were found to escape hepatic inactivatio
basal peripheral venous levels of serotonin, 233 ±
103 ng/ml, increased to 455 ± 127 ng/ml at 10 min.
During endogenous serotonin release, 92 ± 21% of p
venous serotonin was bound to platelets; in contrast, during intraportal serotonin infusion, only
59 ± 18% of serotonin was platelet-bound. The
ability of exogenously administered serotonin to
reproduce the actions of the endogenously released
molecule identically supports the contention that
serotonin plays a major role in the intestinal con
trol of gastric acid secretion.

4572 MECHANISM OF INHIBITION OF GASTRIC ACID SECRETION BY HYPERTONIC SOLUTIONS AND VASOPRESSIN. (Eng.) Limlomwongse, L.; Nophakoon, J.; Thithapandha, A. (Dept. Physiology, Mahidol

Univ., Rama VI Rd., Bangkok 4, Thailand). *Pfluegers Arch.* 366(2/3):159-165; 1976.

The mechanism by which hyperglycemia, hypertonic solutions, and vasopressin affect gastric acid secretion and mucosal blood flow (MBF) was studied in female Fischer rats. Infusion of isotonic saline did not alter acid output and gastric clearance of aminopyrine, whereas hypertonic solutions (20% glucose or 3% NaCl) significantly increased plasma osmolality and decreased acid secretion. With glucose, the gastric volume, free HCl secretory rate and HCl concentration were reduced from 0.28 ± 0.01 to 0.18 ± 0.02 ml/15 min ($p<0.001$), 38.0 ± 2.5 to 19.2 ± 2.1 µEq/g stomach/15 min ($p<0.001$), and 135 ± 4 to 111 ± 7 µEq/ml ($p<0.01$), resp. With NaCl, the corresponding figures were 0.33 ± 0.01 to 0.16 ± 0.01 ml/15 min ($p<0.001$), 37.6 ± 1.9 to 18.2 ± 1.6 µEq/g/15 min ($p<0.001$), and 129 ± 1 to 120 ± 3 µEq/ml ($p<0.01$), resp. Vasopressin at low concentrations (10-1,000 µIU/100 g, i.v.) did not significantly affect gastric secretion. However, higher concentrations (5, 10, 25 mIU/100 g) progressively and significantly reduced acid output. Both hypertonic solutions and vasopressin significantly reduced the MBF, as determined by aminopyrine clearance. Aminopyrine clearance was reduced from 4.7 ± 0.3 to 2.7 ± 0.2 ml/15 min ($p<0.001$) by a single dose of 20% glucose, from 4.9 ± 0.4 to 2.2 ± 0.3 ml/15 min ($p<0.001$) by 3% NaCl, and from 7.1 to 0.8 to 2.6 ± 0.5 ml/15 min ($p<0.001$) by 25 mU vasopressin. However, the ratio of MBF to gastric secretory rate did not significantly change when either the hypertonic solutions or vasopressin was infused. It is concluded that all three agents probably have a direct action on secretion rather than on decreasing MBF.

4573 EFFECT OF PROXIMAL GASTRIC VAGOTOMY ON GASTRIC ACID HYPERSECRETION AND HYPERGASTRINEMIA AFTER MASSIVE SMALL BOWEL RESECTION IN DOGS.

(Eng.) Wolf, S. A.; Dozois, R. R.; Go, V. L. W.; Telander, R. L. (Mayo Clinic, 200 First St. S.W., Rochester, MN 55901). *Surgery* 81(6):627-632; 1977.

To study the effects of proximal gastric vagotomy on acid hypersecretion and hypergastrinemia, fasting and postprandial gastric acid secretion and gastrin were determined in Heidenhain pouch dogs before (C) and after (R) massive enterectomy (5 dogs) and after additional proximal gastric vagotomy (PGV, 3 dogs). Basal acid output was unchanged (C=7 ± 2 µEq/hr; R=11 ± 4 µEq/hr), but postprandially the hourly (3rd-8th hr) and cumulative outputs (C=3.6 ± 0.3 mEq/8 hr; R=7.2 ± 0.4 mEq/8 hr) were significantly increased by resection ($p<0.001$). Similarly, fasting gastrin was unaltered by resection (C=41 ± 2 pg/ml; R=46 ± 8 pg/ml), whereas hourly gastrin concentrations significantly ($p<0.05$) exceeded control values. Increased gastrin correlated linearly ($p<0.02$) with increased acid output. After PGV, basal acid levels remained unchanged (R=4 ± 2 µEq/hr; PGV=9 ± 4 µEq/hr), but postprandial acid output significantly exceeded prevagotomy values at all time periods ($p<0.05$). Cumulative acid output also was increased (R=6.8 ± 0.6 mEq/8 hr; PGV=11.2 ± 0.6 mEq/8 hr; $p<0.001$). Serum gastrin, however, remained unchanged. Hypersecretion of acid from Heidenhain pouches after massive enterectomy is increased further by PGV without a concomitant increase in serum gastrin.

4574 THE EFFECT OF STRESS ON THE GASTRIC MUCOSAL BARRIER IN RATS.

(Eng.) Werther, J. L.; Horowitz, I. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Proc. Soc. Exp. Biol. Med.* 154(3):415-417; 1977.

Acid was instilled in the pylorus-ligated stomachs of male Sprague-Dawley rats subjected to restraint stress to gain information on the role of the gastric mucosal barrier to back-diffusion of hydrogen ions in the pathogenesis of stress ulceration. Test solutions containing a hydrogen ion concentration of 55 mEq/l were used. Hydrogen ion secretion did not decrease in these stressed rats, but there was a significant increase in H^+ back-diffusion across the gastric mucosa ($p<0.001$), which was well correlated with the gross mucosal damage ($r=+0.88$). In rats with a mean back-diffusion level of only -10.65 ± 9.73 µEq/hr, only erythema was present. Rats with a mean H^+ back diffusion level of -40.36 ± 7.87 µEq/hr had moderate ulceration, and rats with the highest H^+ level (-66.10 ± 17.13 µEq/hr) had the most severe ulceration. Abnormal gastric mucosal permeability to hydrogen ion may play a pathogenic role in restraint-stress-induced ulceration.

SECRETION AND METABOLISM

Pancreas

4583 SYNTHESIS AND SUBCELLULAR DISTRIBUTION OF HEPARAN SULFATE IN THE RAT EXOCRINE PANCREAS. (Eng.) Kronquist, K. E.; Elmahdy, A.; Ronzio, R. A. (Johns Hopkins Univ. Sch. Medicine, 725 North Wolfe St., Baltimore, MD 21205). *Arch. Biochem. Biophys.* 182(1):188-196; 1977.

Sulfate-labeled macromolecules synthesized by rat pancreas *in vitro* were isolated, the material was characterized biochemically, and its role in secretion was studied by investigating its subcellular distribution. Tissue fragments and isolated acinar cells from adult Sprague-Dawley rat pancreas rapidly incorporated inorganic $^{35}SO_4{}^{2-}$ into macromolecules. Secretion of labeled macromolecules was stimulated by carbamylcholine chloride. The principal sulfated product synthesized by isolated acinar cells was purified by diethylaminoethyl cellulose chromatography and was identified as heparan sulfate by digestion with purified heparitinase and by deaminative cleavage with nitrous acid. The results of subcellular fractionation of pancreas tissue labeled *in vitro* with $^{35}SO_4{}^{2-}$ showed that sulfate-containing macromolecules were present both in soluble fractions and as tightly bound membrane components. Zymogen granules contained 14% of the total radioactivity incorporated; zymogen granule membranes, 3%; the soluble zymogen granule contents, 7%; microsomes, 30%; mitochondria, 14%; and the postmicrosomal supernate, 25%. Purified $^{35}SO_4{}^{2-}$-labeled zymogen granule membranes had the highest specific radioactivity of any fraction examined. Degradative analysis with nitrous acid indicated that the major sulfated product present in all of the subcellular fractions was heparan sulfate.

4584 PANCREATIC DUCT OBSTRUCTION WITH AN ACRY ATE GLUE: A NEW METHOD FOR PRODUCING PA CREATIC EXOCRINE ATROPHY. (Eng.) Little, J. M.; Lauer, C.; Hogg, J. (Dept. Surgery, Univ. Sydney, Sydney, N.S.W. 2006 Australia). *Surgery* 81(3):243 249; 1977.

The feasibility of producing pancreatic exocrine atrophy with alkyl-alpha-cyanoacrylate glue was tested in 10 healthy dogs. The glue (1.0 ml) was injected under very low pressure into the main pancreatic duct, and the dogs were killed at month intervals up to 7 months postoperatively. This technique led to a reproducible pancreatic atrophy with preservation of the islets. No significant changes were noted in the serum electrolytes, creatinine, proteins, or bilirubin. A 10- to 15-fold rise in serum amylase was noted in each dog o the first postoperative day, but by 3 weeks, this value had returned to the preoperative level. No animal was diabetic, and by a mean period of 4 months postoperatively, the mean weight of the seven dogs maintained for this length of time had increased to the preoperative level. No evidence of chronic pancreatitis was observed at the autops This technique may be useful in the management of human chronic pancreatitis as an alternative to pancreatic resection.

4585 THE EFFECT OF DIBUTYRYL CYCLIC ADENOSINE 5'-MONOPHOSPHATE ON PROTEIN SECRETION FR THE RAT EXOCRINE PANCREAS IN VITRO. (Eng.) Fast, D.; Tenenhouse, A. (Pathophysiologische Institut, Universitat Bern, Bern, Switzerland). *Br. J. Pharmacol.* 58(4):605-612; 1976.

The mechanism by which dibutyryl cyclic AMP potentiates the secretory effect of carbachol was investigated in Wistar rat exocrine pancreas. The pancreases were incubated with 0.5 μCi/ml ^{45}Ca and nonradioactive $CaCl_2$ (5×10^{-6}, 5×10^{-5}, or 5×10^{-4} M). Dibutyryl cyclic AMP (10^{-3} M) potentiated the secretory effect of carbachol only at carbachol concentrations of 10^{-7} M or greater. At 5×10^{-6} M Ca^{2+}, the degree of potentiation was 4.5 and 3.5 for 10^{-6} M and 10^{-4} M carbachol, resp.; at 5×10^{-5} M Ca^{2+} it was 1.2 and 1.4 for these concentrations of carbachol; and at 5×10^{-4} M Ca^{2+}, it was 0.5 and 0.9. Carbachol increased, and dibutyryl cyclic AMP reduced, the rate of ^{45}Ca efflux from the tissue. The ionophore A-23187 stimulated ^{3}H-protein release in the presence of Ca^{2+}, and this effect was potentiated by dibutyryl cyclic AMP; the degree of potentiation was inversely proportional to extracellular concentration of Ca^{2+}. At 10^{-3} M Ca^{2+}, the potentiation occurred only at ionophore concentrations of 10^{-6} M or less. These results support the hypothesis that dibutyryl cyclic AMP potentiates the effect of secretagogues in rat exocrine pancreas by maintaining an elevated intracellular calcium concentration (by inhibiting Ca^{2+} efflux). The results also suggest that the limiting factor in carbachol-stimulated secretion is the intracellular Ca^{2+} concentration.

4586 EFFECTS OF CATECHOLAMINES AND THEIR INHIBITORS ON THE ISOLATED CANINE PANCREAS. I. NORADRENALINE AND ISOPRENALINE. (Eng.) Vaysse, N.; Bastie, M. J.; Pascal, J. P.; Martinel, C.; Fourtanier, G.; Ribet, A. (CHU Rangueil L3, 31400 Toulouse, France). *Gastroenterology* 72(4):711-718; 1977.

The effects of the α adrenergic agonist noradrenalin (2, 20, and 200 μg) and antagonist phenoxybenzamine (15 mg) and of the β adrenergic agonist isoproterenol (2, 20, and 200 μg) and antagonist propranolol (6 mg) were tested on isolated perfused canine pancreas. These effects were compared under basal conditions and under stimulation by a background of secretin (0.5 clinical U/hr) or of cerulein (600-1,200 ng/hr). Noradrenalin induced a strong vasoconstriction (inhibited by phenoxybenzamine), followed by a moderate vasodilation (possibly mechanical). Noradrenalin did not stimulate a resting pancreas and inhibited a pancreas from secreting in response to secretin or cerulein. After phenoxybenzamine, in the absence of vasoconstriction, this latter effect was reversed into a dose-dependent stimulation of hydrelatic secretion, suggesting that noradrenalin had a direct action on the secretory cell. There was no stimulation of protein and no acinar degranulation. Propranolol and atropine did not modify the effectiveness of noradrenalin. Isoproterenol had a weak vasodilatory effect but no effect on the secretion. Adrenergic blocking agents did not alter the response to secretin or cerulein.

4587 EFFECTS OF CATECHOLAMINES AND THEIR INHIBITORS ON THE ISOLATED CANINE PANCREAS. II. DOPAMINE. (Eng.) Bastie, M. J.; Vaysse, N.; Brenac, B.; Pascal, J. P.; Ribet, A. (CHU Rangueil L3, 31400 Toulouse, France). *Gastroenterology* 72(4):719-723; 1977.

The effects of dopamine on the isolated perfused canine pancreas and the possible interaction between secretin and dopamine in the stimulation of water and bicarbonate secretion by the pancreas were studied. Dopaminergic agonists (dopamine, 2, 10, 50, and 250 μg: apomorphine, 1 mg: and noradrenalin, 2, 20, and 200 μg) and inhibitors (haloperidol, 5 mg; pentamethonium, 500 mg; phenoxybenzamine, 15 mg, and atropine sulfate, 10 mg) were tested under basal conditions and under stimulation by a background of secretin (0.1, 0.5, and 10.0 clinical U/hr) or of cerulein (1,200 ng/hr). Low doses of dopamine induced a vasodilation inhibited by haloperidol. Large doses induced a vasoconstriction, presumably by stimulation of α-adrenergic receptors. Dopamine stimulated hydrelatic secretion. The calculated maximal response was about one-half that of secretin. This response was inhibited by haloperidol but not by atropine, pentamethonium, and phenoxybenzamine. No acinar degranulation was observed after stimulation by dopamine. The response to secretin was not altered by haloperidol. It is concluded that blood vessels and pancreatic tissue contain specific receptors to dopamine different from secretin receptors. Secretory response to noradrenalin after phenoxybenzamine was inhibited by haloperidol, suggesting that this effect was mediated by the stimulation of the dopamine receptors of the cells.

4588 THE EFFECTS OF CALCITONIN ON PANCREATIC EXOCRINE SECRETION IN DOGS. (Eng.) Nakashima, Y.; Appert, H. E.; Howard, J. M. (Medical Coll. Ohio at Toledo, Toledo, OH). *Surg. Gynecol. Obstet.* 144(1):71-76; 1977.

The effect of calcitonin on pancreatic secretion was studied in unanesthetized dogs with a Thomas cannula implanted opposite the main pancreatic duct. Pancreatic juice was collected for a 60-min control period, during which time secretion was stimulated by an i.v. infusion of secretin (45 U/hr) and pancreozymin (50 U/hr). Calcitonin (35 μg) decreased the volume, bicarbonate, and enzyme output in the pancreatic juice to about one-half than during the control period. During the 60-min period after calcitonin infusion was stopped, the volume, bicarbonate, and enzyme content of the pancreatic juice increased but remained slightly lower than that of the control period. The infusion of calcium gluceptate, together with secretin and pancreozymin, overcame the inhibitory effect of calcitonin on pancreatic secretion. The results suggest that the mechanism of calcitonin action on pancreatic secretion involves an inhibition of calcium influx into the pancreas.

4589 ACUTE INTERSTITIAL PANCREATITIS IN THE RAT INDUCED BY EXCESSIVE DOSES OF A PANCREATIC SECRETAGOGUE. (Eng.) Lampel, M.; Kern, H. F. (Dept. Anatomy, Univ. Heidelberg, W. Germany).

Virchows Arch. A Patho. Anat. Histol. 373(2):97-117; 1977.

Conscious male Wistar rats were infused via a jugular vein catheter with 5×10^{-6} g/kg/hr cerulein for periods up to 24 hr to determine if there are any destructive pancreatic changes produced by this decapeptide. On macroscopic inspection, a progressive interstitial edema developed in the pancreas from 1 hr of infusion onward and was most marked at 12 hr. This edema was largely reabsorbed after 24 hr of treatment, but the pancreas was considerably indurated by this time. Serum amylase levels increased consistently to reach a 10-fold elevation above controls after 3, 6, or 12 hr of infusion. Premature fusion of condensing vacuoles and secretory granules led to the formation of large vacuoles in the cytoplasm of exocrine pancreatic cells. These vacuoles fused with the lateral and basal plasma membranes and released their contents into the extracellular space. Regular discharge of zymogen granules at the cell apex into the duct system did not occur. Vacuole formation was associated with cytoplasmic destruction of the pancreatic cells. The rate of protein synthesis decreased consistently as a result of these structural alterations, and this change corresponded largely to a reduction of cellular respiration. Release of amylase from isolated pancreatic lobules of cerulein infused animals showed a progressive increase of unstimulated discharge, while *in vitro* stimulation with 5×10^{-6} M carbamylcholine gave secretion patterns of washout kinetics. Stimulated discharge of labeled secretory proteins indicates a progressive reduction in the *in vitro* sensitivity of the pancreatic cells to secretagogues. After 24 hr of infusions of 5×10^{-6} g/kr/hr cerulein, the pancreatic lobules were totally insensitive to the *in vitro* effect of carbamylcholine or cerulein.

4590 STIMULATION OF PANCREATIC SECRETION OF WATER AND ELECTROLYTES BY FUROSEMIDE.

(Eng.) Thomas, F. B.; Sinar, D.; Caldwell, J. H.; Mekhjian, H. S.; Falko, J. M. (N-937 Univ. Hosp., Ohio State Univ., 410 W. 10th Ave., Columbus, OH 43210). *Gastroenterology* 73(2):221-225; 1977.

To test the hypothesis that diuretics may affect water and electrolyte secretion by the pancreas, the effect of furosemide on secretin-stimulated pancreatic secretion was examined in 12 normal subjects using a perfusion method to quantitate pancreatic output. During continuous secretin infusion (0.9 U/kg/hr), secretory volume rose to a steady-state level of 32.5 ± 10.2 ml/min. When a bolus injection of furosemide (20 mg) was given during continuous secretin infusion, the mean secretory volume increased further to a maximum value of 110 ± 14.7 ml/min. Similarly, the outputs of bicarbonate, sodium, and chloride increased significantly after furosemide (5.8 ± 1.6, 11.0 ± 1.6, and 6.6 ± 0.80 mEq/10 min, resp.), unlike those obtained with secretin infusion alone (2.8 ± 1.0, 4.5 ± 1.4, and 2.1 ± 0.85 mEq/10 min). Total bilirubin output fell after furosemide ($p<0.02$), suggesting that the effect of furosemide on secretory volume and electrolyte output was not due to a stimulatory effect on bile flow. Furosemide also had no effect on duodenal water transport. These observations demonstrate that furosemide stimulates pancreatic secretion of water and electrolytes, possibly via inhibition of pancreatic ductal absorption of sodium.

4591 TROPHIC EFFECTS OF GASTRIN ON THE EXOCRI PANCREAS IN RATS.

(Eng.) Reber, H. A.; Johnson, F.; Deveney, K.; Montgomery, C.; Way, L. (Veterans Admin. Hosp., San Francisco, CA 94121). *J. Surg. Res.* 22(5):554-560; 1977.

The trophic effects of chronic endogenous hypergastrinemia were investigated in the rat pancreas, and the functional significance of these effects on pancreatic secretion was studied. In three groups of hypergastrinemic Sprague-Dawley rats with gastrojejunostomy and gastric antrum transplanted to the colon (AT), pancreatic structure and function were studied 2, 6, or 16 weeks postoperatively. Fasting serum gastrin was 658 ± 88 pg/ml in AT animals compared with 87 ± 12 pg/ml in sham-operated controls. Another group of rats prepared with antrectomy and gastrojejunostomy (A) had low serum gastrin concentrations; they were studied 12 weeks postoperatively. Pancreatic juice was collected after i.v. secretin or cholecystokinin (CCK) and was analyzed for $[HCO_3^-]$, $[Cl^-]$, and total protein. Pancreas histology and DNA/RNA/mg of pancreatic protein were the same in all groups. A twofold increase in $[HCO_3^-]$ and volume of secretion at 2 weeks in AT animals suggested that gastrin exerted a trophic effect on the ducts. By 6 weeks, pancreas weight had increased, probably reflecting acinar growth. By 16 weeks, pancreatic secretion was qualitatively similar to the control group, but the pancreas weights were 35% greater, and absolute secretory capacities were 50% greater. In the A animals, pancreas weights and protein secretion were unchanged, but HCO_3^- secretion was impaired. It i concluded that chronic endogenous hypergastrinemia produced functionally significant hyperplasia of both the duct and acinar cells.

4592 BOVINE PANCREATIC PEPTIDE: ACTION ON GASTRIC AND PANCREATIC SECRETION IN DOGS

(Eng.) Lin, T. M.; Evans, D. C.; Chance, R. E.; Spray, G. F. (Lilly Res. Lab., Eli Lilly and Co., Indianapolis, IN 46206). *Am. J. Physiol.* 232(3): E311-E315; 1977.

The actions of bovine pancreatic peptide (BPP), a recently isolated straight-chain peptide containin 36 amino acid residues, on gastric and pancreatic secretions were evaluated in dogs. In addition, BPP was studied to determine if it has hyperglycem hyperkalemic, and diuretic actions similar to glucagon. BPP (40 μg/kg/hr, i.v.) stimulated gastric acid secretion when given alone, but inhibited the submaximal secretion induced by the C-terminal pentapeptide of gastrin. Basal pancreatic secretion of dogs was inhibited by BPP (1-10 μg/kg/hr), and maximal inhibition was about 80%. In dogs stimulated by secretin alone, BPP (1-50 μg/kg/hr) inhibited pancreatic protein secretion (by peak levels of 50%-75%), but often showed a biphasic action on water-bicarbonate response, an initial augmentation followed by reduction. BPP (205 μg/kg/hr) inhibited the pancreatic water-bicarbonate and protein secretions induced by an infusion of secretin plus cholecystokinin (by 40-67% for protein and by 63-91% for bicarbonate). Des-tyrosyl-NH_2 BPP lacking the C-terminal tyrosyl amide failed to inhibit the gastric acid induced by C-terminal pentapeptide of gastrin or the pancreatic secretion induced by secretin. BPP had no hyper- or hypoglycemic, hyperkalemic, or diuretic actions in the dog.

4593 COMPARISON OF PANCREATIC RESPONSES TO PORTAL AND SYSTEMIC SECRETIN AND VIP IN CATS. (Eng.) Konturek, S. J.; Domschke, S.; Domschke, W.; Wunsch, E.; Demling, L. (Medical Acad. Cracow, Cracow, Poland). *Am. J. Physiol.* 232(2): E156-E158; 1977.

The pancreatic bicarbonate responses to secretin and vasoactive intestinal peptide (VIP) administered by the peripheral or portal route were compared in 24 anesthetized cats. Continuous i.v. infusion of graded doses of secretin (0.04-0.68 nmol/kg/hr), stimulated pancreatic volume flow and bicarbonate outputs dose-dependently and was not statistically different when given by either route. VIP infused in graded doses (0.60 to 9.62 nmol/kg/hr) into the peripheral vein produced pancreatic volume flow and bicarbonate outputs not statistically different from those obtained with secretin. In contrast, the biological activity of VIP administered intraportally was reduced by 60% at lower VIP doses (0.60 and 1.20 nmol/kg/hr) and by 40% at 2.40 nmol/kg/hr, but at higher doses it was not significantly changed. This study provides evidence that VIP in the cat is a secretin like full agonist of pancreatic bicarbonate secretion and that it is only partially inactivated by the liver.

4594 PARASYMPATHETIC CONTROL OF PANCREATIC JUICE SECRETION IN THE RABBIT. (Spa.) Lopez, M. A.; Lupiani, M. J.; Murillo, A. (Departamento Interfacultativo de Fisiologia Animal, Universidad de Granada, Granada, Spain). *Rev. Esp. Fisiol.* 32(1):53-58; 1976.

Pancreatic secretion rate and protein concentration of pancreatic juice were determined in anesthetized rabbits (both sexes, 1.8-3 kg) during electrical or chemical stimulation of the vagal nerves with parasympathomimetics or during i.v. administration of atropine sulfate. A slight increase in flow rate during electrical stimulation (15 V/0.5 msec at 25 pulses/sec) continued for 20 min after stimulation; considerable variation was noted in rates among individual animals, but all animals showed an increase. Protein content of pancreatic juice increased markedly. Very similar increases were produced by infusion or injection of the parasympathomimetics acetylcholine (10 μg/kg/min) and pilocarpine (1 mg/kg). These stimulatory effects may be due to vasodilation. Bradykinin (0.1-4 μg/kg), a vasodilator, caused a considerable increase in pancreatic flow, although protein concentration was reduced. Atropine (1 mg/kg) decreased pancreatic secretion flow rate and protein concentration slightly and, when administered prior to pilocarpine, counteracted the stimulatory effect of the parasympathomimetics. Rabbit pancreatic response to vagal nerve stimulation correlated better with responses in carnivores (dogs and cats) than in herbivores (pigs and horses).

4595 THE EFFECT OF FASTING ON THE IN VITRO SYNTHESIS OF AMYLASE IN RAT EXOCRINE PANCREAS. (Eng.) Vieira-Matos, A. N.; Tenenhouse, A. (Dept. de ciencias fisiologicas, Escuela de Medicina U.D.O., Cd. Bolivar, Venezuela). *Can. J. Physiol. Pharmacol.* 55(1):90-97; 1977.

The effect of fasting upon the *in vitro* synthesis and specific activity of amylase (EC 3.2.1.1.) from rat exocrine pancreas was studied. Female Wistar rats were fasted for 72 hr, while another group was given free access to a balanced commercial diet. The rats were sacrificed and a crude pancreatic extract was prepared. Amylase specific activity and the incorporation of L-(^{3}H)-leucine into amylase were measured using immunological techniques. RNA and protein contents, as well as trypsin and chymotrypsin activities, were also measured and were found to decrease only slightly as a result of fasting; however, amylase activity was decreased about 50%. Using rabbit anti-amylase antibodies, a marked decrease in the amount of immunoprecipitable protein was found. L-(^{3}H)-leucine incorporation into the immunoprecipitable protein decreased by approximately 50%, although no difference in the rate of L-(^{3}H)-leucine incorporation into total pancreatic protein from fed and fasted rats was detected. Pulse-labeling experiments with L-(^{3}H)-leucine showed no significant increase in the rate of amylase breakdown, indicating that the decreased incorporation of radioactivity into the pancreatic amylase of fasted rats was due to a decrease in synthesis of amylase. It is concluded that the rate of amylase synthesis is influenced mainly by food intake rather than by the amount of amylase in the tissue.

4596 ACUTE PANCREATITIS WITH HYPERLIPEMIA: STUDIES WITH AN ISOLATED PERFUSED CANINE PANCREAS. (Eng.) Saharia, P.; Margolis, S.; Zuidema, G. D.; Cameron, J. L. (Johns Hopkins Medical Inst., 601 N. Broadway, Baltimore, MD 21205). *Surgery* 82(1):60-67; 1977.

The proposal that hypertriglyceridemia can initiate acute pancreatitis by pancreatic lipase hydrolysis of triglycerides with the local release of large quantities of free fatty acids (FFA) was investigated. An isolated, *ex vivo*, perfused canine pancreatic preparation was used. Control preparations remained normal in gross appearance, gained little weight (18 g), extracted oxygen and glucose, released carbon dioxide, and continued to secrete during a 4-hr perfusion period. Serum amylase remained normal (972 clinical U/100 ml) as did FFA (1.11 mEq/l). When triglycerides were added to the perfusate to increase the serum triglycerides to 1,600 mg%, the glands became edematous, hemorrhagic, and gained considerable weight (52 g) during the 4-hr perfusion period. Serum amylase became markedly elevated (2,624 clinical U/100 ml), as did the serum FFA (29.19 mEq/l). When FFA were added directly to the perfusate, the glands became edematous, hemorrhagic, and gained weight (90 g), but did so much more rapidly than when triglycerides were added. These studies support the concept that hypertriglyceridemia can initiate pancreatic injury, and they suggest that the mechanism may operate through the release of FFA.

4606 IMPROVED ISOLATED LIVER CELL PREPARATION: MONITORING HYDROSTATIC PRESSURE AND RETURN FLOW DURING LIVER PERFUSION. (Eng.) Wittman, J. S., III; Jacobus, K. E. (Roche Res. Center, Hoffmann-LaRoche Inc., Nutley, NJ 07110). *Anal. Biochem.* 79(1/2):58-62; 1977.

The addition of a hydrostatic pressure gauge and a return-flow meter to a perfusion apparatus for the preparation of improved isolated liver cell preparations is described. A hydrostatic pressure gaug is made by attaching transparent vinyl tubing to a meter stick, with the upper end open to atmospheri pressure and the lower end connected to the bubble trap. A flow meter is installed in the return lin between the liver and the perfusate reservoir. Th use of these two gauges can assure that the cannulae are properly placed and that the perfusate is flowing. In addition, they provide data that demonstrate whether digestion is sufficient, and they indicate a blockage. The liver is protected from excessive swelling by allowing the perfusate to fill the pressure gauge while the blockage is being cleared. This apparatus was used to prepare isolated hepatocytes from female Charles River CD rats by perfusion of livers with collagenase-hyaluronidase. The length of time required for digestion varied with different batches of collagenase and ranged from 17 to 33 min. A particular batch was reproducible within about ±10% between livers. Increasing the collagenase concentration decreased the time required for digestion. Perfusion of the livers without hyaluronidase or with Swim's media or 100% oxygen did not affect yield or percentage of viability. However, if the perfusion was terminated before the liver began to lose its structure, increased mechanical manipulation was required to free individual cells, resulting in a decrease in cell yield and percentage of viable cells. Hydrostatic pressure remained fairly constant during the enzymatic digestion. Return-flow rate invariably fell during the perfusion.

4607 CELL KINETICS IN THE LIVER OF RATS UNDER NORMAL AND ABNORMAL DIETARY CONDITIONS: AN AUTORADIOGRAPHIC STUDY BY MEANS OF [^{3}H] THYMIDINE.

(Eng.) Blikkendaal-Lieftinck, L. F.; Kooij, M.; Kramer, M. F.; Den Otter, W. (Dept. Pathology, State Univ., Pasteurstraat 2, Utrecht, Netherlands). *Exp. Mol. Pathol.* 26(2):184-192; 1977.

DNA synthesis in the liver acinus of 4- to 5-week-old male Wistar WU rats fed either a normal diet or a bacon diet was studied autoradiographically by ^{3}H-thymidine labeling. In rats fed a normal diet (21.1% protein, 5.0% fat, 51.9% carbohydrate, 11.5% water, 6.3% ash, and 4.2% fiber), the DNA synthetic index was 4.3% on the first day after ^{3}H-thymidine injection and decreased gradually over a 150-day period to a value of about 1.5%. At 3 hr after the injection of ^{3}H-thymidine, most of the labeled nuclei were seen in zone I of Rappaport's simple liver acinus, and as time proceeded, there was a shift of the peak value of labeled nuclei in the direction of the terminal hepatic venule (THV) over the 150-day observation period. When rats were fed a bacon diet (3.5 ± 1.4% protein, 86.1 ± 6% fat, 12.1 ± 4.3% water, and 0.12 ± 0.09% ash) for 30 days, the DNA synthetic index was only 0.2%, and it remained at this level up to 150 days after injection. The cumulative frequency of the labeled nuclei along the hepatic plate showed that, in this experiment also, labeled nuclei moved to the THV. When the rats maintained on the 30-day bacon diet were given a normal standard diet, the DNA synthetic index increased after the 1st day on the normal diet and reached a peak of greater than 5% after about 2 days. The peak value of DNA synthesizing nuclei was in zone II after 2 days of a normal diet. After 1 week, the peak value moved to zone I. It thus appears that DNA synthesis in the rat liver can be depressed by a 30-day bacon diet and that the synthesis can be restored by a normal standard diet within 2-3 days.

4608 RESEARCH ON INTERAZYGOPORTAL DISCONNECTION THROUGH VOSSCHULTE'S RING. EXPERIMENTAL STUDY IN THE DOG.

(Fre.) Germain, M.; Martin, E. (3, rue de l'Harmonie, 75015 Paris, France). *J. Chir. (Paris)* 111(3):377-388; 1976.

Twenty-nine dogs with esophageal varices due to portal hypertension underwent interazygoportal disconnection with endoprothesis using Vosschulte's rings (VR). The rings had an outer diameter of 12 or 16 mm. Animals were anesthetized with penthotal (2 cg/kg), and intubated with oxygen prior to the procedure. Eight dogs served as controls and received portal vein ligature to induce portal hypertension 3 weeks prior to the experiment. Esophageal varices did not develop in six of the controls; the remaining animals died (1 of barbiturate coma and 1 of esophageal perforation). Nine of the 20 dogs that received a 12-mm VR either had to be sacrificed or died within 1 month of surgery. Eight of the nine dogs given a 16-mm VR survived for 4-5 months. Morbidity in the dogs receiving a VR was marked; of the 19 surviving animals, 18 presented with diarrhea and regurgitation. Esophagogastric transit produced an immediate subcardiac stenosis in 18 animals, sometimes with dilatation of the substructural esophagus. Macroscopic examination of esophagogastric specimens showed a subcardiac indurated ring. Histology revealed normal esophageal structure. In the stricture zone, no subserous or submucosal arteries and veins of large diameter were noted. In treating esophageal varices with interazygoportal disconnection, optimal results were obtained with VR rings of the same diameter as the esophagus. Morbidity due to regurgitation may be reduced by early instrumental dilatation.

4609 MICROCIRCULATION STUDIES OF EXPERIMENTAL LIVER REGENERATION.

(Fre.) Bourgeon, R.; Isman, H.; Brisard, M.; Letourneau, J. (Clinique chirurgicale, Hopital Saint-Roch, 5, rue P.-Devoluy, 06000 Nice, France). *Rev. Fr. Gastroenterol.* (125): 45-47; 1977.

Microcirculation studies of experimental liver regeneration (LR) were performed in 45 Fauve de Bourgogne rabbits that had been subjected to ablation of the caudal and lateral left liver lobes. Groups of five rabbits were sacrificed weekly. Immediately before sacrifice, the hepatic artery, portal vein, and biliary ducts were catheterized *in vivo*, and China ink was injected into the hepatic artery, carmine/gelatin was injected into the portal vein, and the biliary ducts were filled with trypan blue gelatin. Ectasia of the biliary ducts and intense dilation of the parietal arterial plexus marked the beginning of LR. Hepatocyte multiplication occurred by stages as arterial penetration crossed the different zones of the lobules. The terminal stage was marked by the arrival of arterial blood in the centrolobular veins, sometimes by the porto-subhepatic arterial shunts. Supplementary subhepatic veins appeared in lobules that became very large due to hepatocyte proliferation. New spaces partitioned the large lobules into smaller ones in an organized fashion, which marked the end of LR. In conclusion, LR is essentially hepatocytic and it proceeds (for the biliary ducts and vessels) by initial ectasia of the lumen.

4610 DIURNAL BIOLOGICAL RHYTHMS OF THE GRANULATION TISSUE CELLS IN A WOUND OF THE LIVER.

(Rus.) Arend, Yu. E.; Torpats, T. Yu. (Medical Faculty Tartu, Univ. Tartu, USSR). *Arkh. Anat.* (10):58-61; 1976.

The diurnal biological rhythms of granulation tissue cells (fibroblasts) were studied in a wound of the liver of 37 young mature male Wistar rats (first series) and 44 young mature female Wistar rats (second series), 4 and 9 days, resp., after the injury. The first series of animals, injected with ^{3}H-methionine, were killed in groups of 6-7 every 4 hr during one day, and the second series, injected with ^{35}S-sulfate in groups of 3-4 rats, during two days. Diurnal changes in the number of mitotically dividing and DNA-synthesizing fibroblasts were found in the first series of rats. Maximum mitosis was observed in the period from the mid-day to 4 p.m., decreasing to a minimum at 8 p.m., and the second peak of mitoses appeared from midnight to 4 a.m. with the further decrease at 8 a.m. The maximum intensive synthesis of DNA took place at 8 a.m., i.e., 4 hr before the first peak of mitoses. In the second rat series (9 days after injury), the same diurnal rhythm of mitoses in the first day was found; in the second day the second peak of mitoses was absent. Synthesis of proteins and sulphated mucopolysaccharides in fibroblasts was maximum at 4 p.m. There appears to be a definite rhythm in mitotic activity of the granulation tissue cells and in the synthesis of DNA and sulphated mucopolysaccharides in the rat liver wounds. The degree of coordination requires further study.

4611 DRUG METABOLISM IN ADULT RAT HEPATOCYTES IN PRIMARY MONOLAYER CULTURE. (Eng.)

Guzelian, P. S.; Bissell, D. M.; Meyer, U. A. (Medical Coll. Virginia, Box 217, MCV Station, Richmond, VA 23298). *Gastroenterology* 72(6):1232-1239; 1977.

Cytochrome P-450 and microsomal oxidase activities were examined in adult rat hepatocytes during the first 48 hr after the initiation of monolayer culture. In the 24- to 48-hr period immediately following preparation and culture of the isolated parenchymal cells, the level of cytochrome P-450, measured in extracts of cell homogenates, declined to less than 20% of its *in vivo* level, whereas NADPH-cytochrome *c* reductase activity was only moderately reduced and glucose-6-phosphatase activity remained unchanged. The activity of aminopyrine-*N*-demethylase and aniline hydroxylase also fell, paralleling the level of cytochrome P-450. By contrast, *p*-nitroanisole *O*-demethylase activity was unchanged in the cultured hepatocytes despite evidence (type I binding spectrum, NADPH requirement, inhibition by carbon monoxide or by SKF 525A [a competitive inhibitor of cytochrome P-450-mediated drug metabolism]) that *p*-nitroanisole *O*-demethylas is a cytochrome P-450-dependent enzyme. In cultur as *in vivo*, aromatic polycyclic hydrocarbons stimulated *p*-nitroanisole *O*-demethylase and aryl hydrocarbon (benzo[*a*]pyrene) hydroxylase activities; however, this effect was not accompanied by a detectable increase in total carbon monoxide-binding hemoprotein. The data indicate that the profile o microsomal oxidase enzymes and their control undergo striking changes as hepatocytes adapt to cell culture.

4612 PHYSIOLOGY OF BILIARY EXCRETION OF ROENTGENOGRAPHIC CONTRAST MEDIA. (Ger.) Fucl

W. A. (Institut fur Diagnostiche Radiologie, Inselspital, CH-3010 Bern, Switzerland). *Radiologe* 17 (2):64-69; 1977.

Studies of the transport, resorption, uptake, and excretion of contrast agents used for p.o. (Na iopanoate, Na tri-iopanoate, Na, Ca opodate, Na ioben amate, Na bunamiodyl, and Na tyropanoate) and i.v. cholecystocholangiography (water-soluble iodipamid ioglycamide, iotroxamide, and iodoxamide) are reviewed. Passive diffusion through the intestinal mucosa is believed to be responsible for the intestinal resorption of p.o. contrast agents; bile aci increase the solubility of these agents. Selectiv uptake is due to membrane transport and binding to ligandins (Y and Z protein) in the hepatocyte cytoplasm. P.o. contrast agents are conjugated in the liver to water-soluble glucuronic acid conjugates, which facilitates their transport through the canalicular hepatocyte membrane. Canalicular excretion is due to an active anionic transport system, which has a transport maximum. The biliary excretion of iopanoate and the radiological visualizati of the gallbladder are improved by activation of the enterohepatic circulation of bile acids. The biliary excretion of i.v. contrast agents is associated with intense choleresis. Most of the p.o. contrast agent reaches the gallbladder, where it becomes concentrated due to water resorption throu the gallbladder mucosa.

4613 INTERACTION OF BROMOSULFOPHTHALEIN WITH MITOCHONDRIAL MEMBRANES--UPTAKE OF BROMOSULFOPHTHALEIN AND EFFECT ON ANS-FLUORESCENCE.

(Eng.) Burr, R.; Schwenk, M.; Pfaff, E. (Inst. Toxicology, Univ. Tubingen, D-7400 Tubingen, W. Germany). *Biochem. Pharmacol.* 26(6):457-460; 1977.

The interaction of BSP with mitochondrial membranes and the effect of BSP on 8-anilinonapthalene 1-sulfonic acid (ANS)-fluorescence was studied in Spragu Dawley rat livers. When BSP was added to a mitochondrial suspension, its free concentration was rapidly decreased by uptake. The time course was very fast (complete within 20 sec) and could not be resolved by the centrifugal filtration technique Scatchard plots of a series of uptake experiments at constant mitochondrial concentrations showed a concave curvature, indicating that the affinity continuously decreases. The decrease in binding affinity is ascribed to an increased negative surface charge resulting from insertion of the negatively charged BSP molecule into the hydrophilic-hydrophobic interphase of the membrane and rendering further binding of anionic molecules more difficult. The binding capacity of mitochondria was found to be as high as, or greater than, 150 nmol/mg protein. Even at these high concentrations, binding was reversible, and the inner membranes of mitochondria were not disrupted, since mitochondria were still centrifugable. BSP uptake depended upon the energetic state of the mitochondria; in the de-energized state, a little more of the dye was taken up than in the energized state. When BSP was added to a mitochondrial suspension containing ANS, the ANS-fluorescence decreased. Above 5 nmol/mg protein, there was a logarithmic decrease with increasing BSP concentrations. The fluorescent dye was released from the mitochondria to the same extent as fluorescence decreased.

4614 HEPATOTOXICITY OF CHENODEOXYCHOLIC ACID: A HISTOPATHOLOGICAL AND ULTRASTRUCTURAL STUDY IN RABBITS.

(Por.) Grimaldi Filho, G. (Departamento de Patologia de UFBa, Anexo I da Faculdade de Medicina, Rua Padre Feijo, 31, 40000 Salvador BA, Brazil). *Arq. Gastroenterol.* 14(2):76-82; 1977.

Chenodeoxycholic acid (50 mg/150 g diet/day) was fed to groups of eight female rabbits for 30 or 60 days; controls received a standard diet. Light microscopy of the liver tissue revealed in the 60-day group severe proliferation of the biliary canals, biliary and parenchymal lesions, portal fibrosis, and one case of cholestasis. The 30-day hepatotoxic effects were similar but more moderate, except for severe portal fibrosis and inflammatory infiltration. Electron microscopy of liver tissue from the 60-day group showed extensive damage to the biliary canaliculi, the presence of autophagocytic vesicles, intrahepatic cholestasis, and an excess of intrahepatic triglycerides and biliary pigments. The 30-day group showed severe hyperplasia of the smooth endoplasmic reticulum. The primary effects of chenodeoxycholic acid in the liver are ultrastructural modification and deactivation of the reticuloendothelial enzyme systems, which lead to intrahepatic cholestasis and the other observed effects.

4615 HEPATIC STORAGE AND BILIARY TRANSPORT MAXIMUM OF TAUROCHOLATE AND TAUROCHENODEOXYCHOLATE IN THE DOG.

(Eng.) Poupon, R.; Poupon, R.; Dumont, M.; Erlinger, S. (Hopital Beaujon, F 92110 Clichy, France). *Eur. J. Clin. Invest.* 6(6):431-437; 1976.

Experiments were performed on anesthetized dogs after depletion of the endogenous bile acid pool to validate the multiple infusion method previously used for the study of hepatic BSP transport and to obtain estimates of the relative storage capacities and secretory transport maxima for taurocholate (TC) and taurochenodeoxycholate (TCDC). Bile was collected continuously to prevent recirculation of bile acids and to measure their secretion rates. TC and TCDC were infused i.v. into dogs at three different rates, and serum bile acid concentrations were determined at intervals of 10 min. In the last 30 min of each infusion period, serum bile acid concentration changed linearly with respect to time, with linear correlation coefficients ranging from 0.95 to 0.99. The mean hepatic relative storage capacities for TC and TCDC were 0.16 ± 0.07 μmol and 0.09 ± 0.03 μmol (μmol/l/kg body weight), resp. The mean secretory transport maximum (in μmol/min/kg body weight) of TC was 4.84 ± 1.24 when calculated and 4.50 ± 0.81 when measured, and of TCDC was 3.56 ± 0.06 by calculation and 3.29 ± 0.09 by measurement. The value of the secretory transport maximum was slightly higher and the relative storage capacity was lower with the multiple infusion method as compared with direct measurement of biliary secretion. The biliary secretion of bile acids achieved a maximal rate 20 min after the start of infusion and was independent of the serum bile acid concentration. The procedure is not applicable to man because of potential toxicity due to the high concentration (220-1,000 μmol/l) of serum bile acid employed.

4616 EVIDENCE FOR CARRIER PROTEINS IN BILE ACID SYNTHESIS. THE EFFECT OF SQUALENE AND STEROL CARRIER PROTEIN AND ALBUMIN ON THE ACTIVITY OF 12α-HYDROXYLASE.

(Eng.) Grabowski, G. A.; McCoy, K. E.; Williams, G. C.; Dempsey, M. E.; Hanson, R. F. (Gastroenterology Unit, Univ. Minnesota, Minneapolis, MN 55455). *Biochim. Biophys. Acta* 441(3):380-390; 1976.

The possibility that carrier proteins are involved in bile acid synthesis was investigated using rat liver homogenates. The 105,000 x *g* supernatant fraction contained heat-stable proteins that bound the bile acid precursor, 7α-hydroxy-4-cholesten-3-one and increased the amount of 7α,12α-dihydroxy-4-cholesten-3-one formed by the microsomal enzyme, 12α-hydroxylase. Subsequent studies were carried out to determine if squalene and sterol carrier protein or albumin, two lipid-binding proteins present in the 105,000 x *g* supernatant fraction of rat liver homogenates, are responsible for the effects seen with this fraction. Squalene and sterol carrier protein bound several water insoluble bile acid precursors, including 7α-hydroxy-4-cholesten-3-one, and increased the apparent activity of 12α-hydroxylase. Squalene and sterol carrier protein, however, did not bind either cholic acid or chenodeoxycholic acid. Rat serum albumin also bound 7α-hydroxy-4-cholesten-3-one and increased the apparent activity of 12α-hydroxylase. Kinetic analysis indicated that the apparent stimulation of 12α-hydroxylase by squalene and sterol carrier protein and albumin was due to increased solubilization of the substrate, 7α-hydroxy-4-cholesten-3-one. These studies indicate that bile-acid precursor carrier proteins are present in the 105,000 x *g* supernatant fraction of rat liver homogenates and suggest that squalene and sterol carrier protein or albumin may participate as carrier proteins in bile acid synthesis.

4617 IN VITRO EFFECT OF FREE BILE ACIDS ON THE BILE CANALICULAR MEMBRANE PHOSPHOLIPIDS IN THE RAT. (Eng.)

Yousef, I. M.; Fisher, M. M. (Dept. Pathology, Univ. Toronto, Ontario, Canada M5S 1A8). *Can. J. Biochem.* 54(12):1040-1046; 1976.

The effect of free bile acids on bile canalicular membrane phospholipid solubilization was studied to understand the origin of biliary lipids. Plasma membranes (PM) and bile canalicular membranes (BCM) were fractionated from liver cell plasma membranes, and their aliquots were incubated with cholic (CA), deoxycholic (DOCA), and chenodeoxycholic (CDCA) acids at bile acid/membrane phospholipid mole ratios of up to 100. Phospholipid (PL) solubilization from the plasma membranes and microsomes was linear and nonselective while that from BCM was biphasic and selective. About 60% of the total PL of microsomes, 30% of the PL of the PM, and 20% of the PL of the BCM were solubilized at a CA/PL mole ratio of 100 ($p<0.001$). Complete solubilization of the microsomal and PM lipids, at a bile acid (DOCA and CDCA)/PL mole ratio of 20 and 40, resp.; the slope of the solubility curve for the segments of the curve for 0-50% and 50-100% solubilization were similar. However, for the BCM, the slope of the curve (using DOCA or CDCA) representing 0-50% solubilization was six times greater than that of the curve representing 50-100% solubilization. Phosphatidyl choline and phosphatidyl ethanolamine made up 90% of the PL solubilized from the BCM at a bile acid (DOCA or CDCA)/membrane PL mole ratio sufficient to solubilize 50% of the total PL. These initial PL (molecular species and fatty acid components) solubilized from the BCM are similar to those of bile of the same animal but are unlike those solubilized at higher bile acid/PL mole ratios. On the basis of previous and present work the origin of the bile lipids in the BCM is suggested.

4618 ACTION OF THREE BILE ACIDS ON HEPATIC AND INTESTINAL CHOLESTEROGENESIS IN THE RAT. (Eng.)

Reynier, M. O.; Marteau, C.; Vigne, J. L.; Mule, A.; Crotte, C.; Gerolami, A. (Institut National de la Sante et de la Recherche Medicale INSERM U 31, 46, chemin de la Gaye, 13009 Marseille, France). *Lipids* 12(3):254-257; 1977.

The inhibitory actions of sodium taurocholate, sodium taurochenodeoxycholate, and sodium taurodehydrocholate on cholesterol synthesis were compared in male Wistar rats during acute interruption of bile enterohepatic circulation. Acetate incorporation into cholesterol in the livers of rats infused with sodium taurocholate (7.5 μmol/100 g/hr) and killed at noon was the same as in controls; cholesterol synthesis was also similar in control and experimental rats treated with taurocholate and killed at midnight. Similarly, sodium taurodehydrocholate (20 μmol/100 g/hr) was without effect. In the liver, taurochenodeoxycholate (7.5 μmol/100 g/hr) prevented the increase in cholesterol synthesis induced by biliary drainage. The jejunal cholesterol synthesis was reduced by taurocholate and taurochenodeoxycholate but was not modified by taurodehydrocholate infusion. The results show that the effects of bile acids on cholesterol synthesis are related to their structures. Since taurodehydrocholate, which does not form micelles at the concentrations used, did not have any effect on cholesterol synthesis, the inhibitory action of bile salts on intestinal cholesterogenesis may depend on their detergent properties.

4619 EFFECT OF FAT INTAKE ON CHOLESTEROL TURNOVER AND BILE ACID FORMATION. (Eng.)

Iritani, N.; Fukuda, E.; Ibamoto, K. (Tezukayama Gakuin Coll., Sumiyoshi-ku, Osaka 558, Japan). *J. Nutr. Sci. Vitaminol. (Tokyo)* 23(1):35-42; 1977.

The effects of varied amounts of dietary fat on overall cholesterol metabolism were investigated in male Wistar rats fed one of three sucrose diets: one fat-free, one containing 3% fat, and one containing 10% fat. The fat in these diets had a balanced composition of fatty acids. After 1 week on one of the diets, the rats received 5 μCi $^3H(G)^2$-cholesterol, i.p. The excretion of neutral sterols, bile acids, and radioactivity was determined in feces collected for 1- to 7-day periods after injection. The coprostanol excretion was similar in all groups, and the bile acid excretion increased with increasing fat intake; however, the excretion of (^3H)-cholesterol in the 3% fat group (35.6 mg/28 days) was greater than that in the fat-free group (33.9 mg/28 days); cholesterol excretion in the 10% fat group was less than that in the fat-free group (27.4 mg/28 days). Consequently, the sp cific radioactivity of bile acids was lower in the group (6.2 counts/min [cpm] x 10^3/mg) than in the 3 group (11.2 cpm x 10^3/mg) and in the fat-free group (11.8 cpm x 10^3/mg). The half-life of labeled cholesterol was 12.6, 16.0, and 22.2 days for the 3%, 10% fat, and fat-free groups, resp. A low-fat diet of about 3% fat is more useful in eliminating cholesterol by increasing the formation of bile acids to emulsify fat than is a fat-free diet. In the 10% fat group, however, the enlarged pool size of bile acid probably delayed cholesterol metabolis to bile acids.

4620 ULTRASTRUCTURE OF GALLSTONES PRODUCED IN MICE FED A HIGH CHOLESTEROL DIET. (Eng.)

Saland, L. C.; Napolitano, L. M. (Univ. New Mexico Sch. Medicine, Albuquerque, NM 87131). *Anat. Rec.* 187(2):207-218; 1977.

The gallstones induced in female mice by a high cholesterol-cholic acid diet were examined by transmission electron microscopy after glutaraldehyde-digitonin fixation. Electron micrographs of gallbladder contents from animals fed the diet for 2 months revealed layered structures and considerable amorphous material. Some areas exhibited smal rounded substructures that appeared to be isolated from larger layered areas. Close examination of larger layered structures within fixed pellets revealed areas of needle-like spicules or whorls in their centers. Gallbladder contents of mice kept on the high cholesterol diet for 5-6 months contained ultrastructural features similar to those observed in animals sacrificed earlier. In addition, occasional rectangular, hexagonal, or parallelogram-shaped objects, suggesting crystals, were observed. The results suggest that the layered appearance of gallstones arises by cohesion of material rich in cholesterol to form more ordered structures.

4621 BILIARY SECRETION OF COPPER IN HEALTHY MAN. QUANTITATION BY AN INTESTINAL PERFUSION TECHNIQUE. (Eng.) van Berge Henegouwen, G. P.; Tangedahl, T. N.; Hofmann, A. F.; Northfield, T. C.; LaRusso, N. F.; McCall, J. T. (Nijmegen Univ. Sch., St. Radboud Hosp., Nijmegen, Netherlands). *Gastroenterology* 72(6):1228-1231; 1977.

The 24-hr biliary copper output was determined in 14 subjects with normal hepatic and gallbladder function, using a duodenal perfusion technique that permitted a normal daytime eating pattern of three liquid meals and an overnight fast. Daily biliary output was also determined by direct measurement on four 24-hr bile collections from three patients with complete biliary diversion; in four patients dietary copper intake and fecal copper output were also determined. A mean bile copper output of 25 ± 13 μg/kg/day (1.7 ± 0.8 mg) was obtained in 19 perfusion studies in the 14 subjects; the range was 9.0-53.0 μg/kg/day. The values in the 24-hr bile collections were similar to those obtained using the perfusion method. Biliary copper output was similar during the day and night, and there was no correlation between hourly rates of copper output and hourly rates of bile acid output, nor was there any correlation between daily copper output and daily bile acid output. The similar values for dietary intake, biliary output, and fecal output provide additional support for the view that in healthy man, copper balance is maintained by biliary secretion and subsequent fecal excretion of copper that has been absorbed in the stomach and proximal duodenum

4622 STIMULATION OF HEPATIC PHOSPHATIDATE PHOSPHOHYDROLASE ACTIVITY BY A SINGLE DOSE OF ETHANOL. (Eng.) Savolainen, M. J. (Dept. Medical Biochemistry, Univ. Oulu, Kajaanintie 52 A, SF-90220 Oulu 22, Finland). *Biochem. Biophys. Res. Commun.* 75(2):511-518; 1977.

An acute ethanol load (5 g/kg) given by gastric intubation to fasted male Long-Evans rats caused a significant increase in phosphatidate phosphohydrolase activity in the soluble fraction of the liver, with the activity being increased twofold at 8 hr and threefold at 16 hr after ethanol administration, in comparison with controls. At 24 hr (about 2 hr after the disappearance of ethanol from the blood), the enzyme activity was still 50% higher than in controls ($p<0.0025$); at 36 hr, there was no difference between ethanol-treated and control enzyme activity. The increase in phosphatidate phosphohydrolase activity in ethanol-treated rats was followed by an accumulation of neutral glycerolipids in the liver, with the hepatic triacylglycerol level at 24 hr after ethanol administration being greater than 15 μmol/g wet weight, as compared to less than 5 μmol/g before ethanol treatment. Assays of cytoplasmic phosphatidate phosphohydrolase activity, using ^{14}C-labeled microsome-bound phosphatidic acid as substrate, showed the activity at 16 hr after ethanol administration to be increased from a control level of 1.71 ± 0.35 to 5.28 ± 0.16 nmol of diacylglycerol formed/sec/g wet weight of liver ($p<0.001$). When 0.1 mCi of (1,3-^{3}H)-glycerol was injected into the portal vein of rats at 0.5 or 16 hr after ethanol administration (5 g/kg), the pattern of labeled glycerol was found to be significantly different from that of control rats at 16 hr. The pattern of radioactivity incorporation into intermediates of hepatic glycerolipid synthesis showed an ethanol-induced cross-over point between phosphatidic acid and diacylglycerol, i.e., in the step catalyzed by phosphatidate phosphohydrolase. This cross-over was observed only when the phosphatidate phosphohydrolase activity was increased.

4623 EFFECT OF CHRONIC ETHANOL ADMINISTRATION ON LIVER ALCOHOL DEHYDROGENASE ACTIVITY IN MICE. (Eng.) Dippel, C.; Ferguson, J. H. (Dept. Biological Sciences, Univ. Idaho, Moscow, ID 83843). *Biochem. Pharmacol.* 26(5):441-442; 1977.

The induction effect of chronic ethanol consumption on alcohol dehydrogenase activity was studied in male Swiss-Webster mice that consumed 15% ethanol in the drinking water from their 21st to 73rd or 74th day of life. Ethanol drinking produced a 20% increase in hepatic alcohol dehydrogenase activity over that in controls ($p=0.015$). The results support the concept that alcohol dehydrogenase activity is altered in response to chronic ethanol exposure at moderate doses.

4624 EFFECT OF ACUTE ETHANOL INTOXICATION ON THE NEURAMINIDASE ACTIVITY OF RAT LIVER GOLGI APPARATUS. (Eng.) Kishore, G. S.; Carubelli, R. (Univ. Oklahoma Health Sci. Center, Oklahoma City, OK 73104). *Biochim. Biophys. Acta* 497(G64): 101-111; 1977.

Neuraminidase and galactosyltransferase were investigated in the Golgi (Gt) apparatus and in the three fractions of increasing density (GF$_1$, GF$_2$, and GF$_3$) isolated from the microsomal fraction of rat liver homogenates by flotation in a discontinuous sucrose density gradient. Fifty percent decreases in neuraminidase content (U/g liver) and specific activity (U/mg protein) were observed in the Golgi as well as in the three fractions isolated at 45 min, 90 min, 180 min, and 16 hr after administration of a single p.o. dose of 50% aqueous ethanol (0.6 g/100 g). Colchicine administration (0.5 mg/100 g, i.p.) caused a similar loss of neuraminidase activity; however, the effect of ethanol plus colchicine was not additive. Golgi galactosyltransferase activity increased following ethanol administration, but, unlike previously reported results, significant increases in total activity and specific activity were already evident 90 min after ethanol ingestion (69.46 ± 10.22, 3.48 ± 1.12, 16.93 ± 1.93, and 41.15 ± 5.33 U/g in control fractions of Gt, GF_1, GF_2, and GF_3, resp., increased to 108.19 ± 1.21 U/g [$p<0.01$], 16.80 ± 3.58 U/g [$p<0.025$], 30.65 ± 4.03 U/g [$p<0.025$], and 61.32 ± 5.73 U/g [$p<0.05$], resp.). In contrast with the decreased values observed in Golgi, the total particle-bound neuraminidase was significantly elevated following ethanol administration. Ultrastructural studies revealed increased lysosomal content and detachment of polysomes from the rough endoplasmic reticulum. The low levels of Golgi neuraminidase probably reflect an accelerated and preferential segregation of acid hydrolases from Golgi apparatus into the lysosomal compartment. This enhanced production of lysosomes appears to be required for the increased autophagic processes needed to dispose of altered subcellular organelles in the ethanol-damaged cells.

4625 EFFECT OF ETHANOL ADMINISTRATION ON THE ACTIVITY OF HEPATIC LYSOSOMAL ENZYMES.

(Eng.) Mezey, E.; Potter, J. J.; Ammon, R. A. (Baltimore City Hosp., Baltimore, MD). *Biochem. Pharmacol.* 25(23):2663-2667; 1976.

The effect of acute, short-term, and prolonged chronic administration of ethanol on the total and free activity of hepatic lysosomal enzymes was investigated in male rats. The acute administration of ethanol (4 g/kg, p.o. b.i.d.) as a 40% solution and the chronic administration of ethanol as 36% of the calories in the diet for 1 month did not result in any changes in lysosomal enzymes. Ethanol feeding for 6 months resulted in increases in the total activities of several enzymes as compared with controls: β-glucuronidase (0.76 ± 0.036 versus 1.14 ± 0.164 μmol/g liver/min, $p<0.05$), β-*N*-acetylglucosaminidase (3.69 ± 0.323 versus 5.30 ± 0.537 μmol/g liver/min, $p<0.05$), and arylsulfatase A (3.52 ± 0.124 versus 4.64 ± 0.316 μmol/g/min, $p<0.01$), measured in the homogenates. Increases in the specific activities of these enzymes plus acid phosphatase measured in the lysosomal fraction were also noted (31.5 ± 1.75, 599.9 ± 52.50, 287.8 ± 54.49, and 536.4 ± 41.61 nmol/mg protein/min, resp., in controls versus 51.2 ± 6.68, 1,200.5 ± 244.40, 540.0 ± 107.8, and 812.0 ± 65.3 nmol/mg protein/min, resp., in animals fed ethanol for 6 months). In addition, there were increases in the free activities of β-glucuronidase and acid phosphatase measured in the homogenates. Hyaluronidase was not changed by ethanol feeding. The increases in lysosomal enzymes were accompanied by histologic changes consisting only of mild fatty infiltration. The increases in total and free lysosomal enzymes may explain the increased activity of lysosomal enzymes found in the serum of chronic alcoholic patients.

4626 METABOLISM OF ETHANOL AND SORBITOL IN CLOFIBRATE-TREATED RATS.

(Eng.) Poso, A. R.; Hillbom, M. E. (Coll. Veterinary Medicine, Hameentie 56, SF-00550 Helsinki 55, Finland). *Biochem. Pharmacol.* 26(4):331-335; 1977.

The rates of ethanol and sorbitol removal and the cytoplasmic and mitochondrial redox states of the liver were determined in female Sprague-Dawley rat pretreated with clofibrate (ethyl-α-*p*-chlorophenox isobutyrate, 0.2 g/kg, s.c.) for 2-15 days. The rats received 2 M ethanol (10 mmol/kg/, i.v.) with or without sorbital (10 mmol/kg). Clofibrate administration for 2 days significantly increased the liver ethanol elimination ($p<0.05$), but this effect disappeared when clofibrate treatment was continued. A significant increase in liver mass took place within a week ($p<0.001$), but this cann explain the initial increase in ethanol removal. The rate of sorbitol removal was significantly decreased by clofibrate ($p<0.01$), and a decrease in liver sorbitol dehydrogenase activity ($p<0.05$) was also observed. The sum of ethanol removal and sorbitol removal, when they were simultaneous metabolized, was significantly decreased in clofibrate-treated rats as compared with controls. Sorbitol inhibition of ethanol elimination was increased (from 25% to 31-47%) but ethanol inhibition of sorbitol elimination was abolished by clofibrate administration. Ethanol and sorbitol cau similar changes in cytoplasmic (lactate/pyruvate) and mitochondrial (β-OH-butyrate/acetoacetate) redox states of clofibrate-treated rat liver, as has been previously observed in livers of control animals.

4627 ABSORPTION, DISTRIBUTION AND EXCRETION A DIHYDROXYDIBUTYL ETHER LABELLED WITH ^{14}C IN ANIMALS.

(Eng.) Porta, R.; Fregnan, G. B (Istituto Luso Farmaco d'Italia, s.r.l., Via Carn 26, I-20 132 Milan, Italy). *Arzneim. Forsch.* 27(118-122; 1977.

The absorption, distribution, and elimination of ^{14}C-labeled dihydroxy-dibutyl ether (DHBE) was studied in rats, dogs, and monkeys. ^{14}C-DHBE was administered p.o. at 500 mg/kg in Sprague-Dawley rats or at 30 mg/kg in dogs and monkeys. The tota recovery of radioactivity from urine, feces, gast intestinal tract (tissues + contents), tissues, a carcass ranged from 89.4 to 108% at 10 min to 24 after administration in rats. Ten minutes after administration, the presence of radioactivity was noted in all tissues (blood, brain, heart, kidney liver, lung, skeletal muscle, skin, spleen, and bile) of rats, the highest portions being found i the kidneys and liver (1,122.5 ± 178.7 μg/ml and 707.5 ± 131.6 μg/ml, resp.). The concentration o radioactive material reached peak values in the tissues within the first 30 min and then sharply decreased between the 1st and 2nd hr. The half-life in blood was only 43 min. The amount of ^{14}C-DHBE present in the gastric contents dropped shar to low levels 10-30 min after treatment, while th present in the intestinal contents never increase by more than 5% of the total radioactivity. The radioactivity of the content of the small intesti was always greater than that found in the large intestine and remained at the same level for at least 3.5 hr. These data, together with the find of relatively large amounts of radioactivity in th bile (1,788.2 ± 163.6 and 554.1 ± 26.0 μg/ml at 6 and 120 min, resp.) and of small amounts in the feces, indicate that enterohepatic reabsorption of DHBE occurs. DHBE was excreted mainly by the kidneys, up to 95.6% being found in the urine 24 hr after administration. In dogs, the DHBE half-life was about 1.5 hr. The kidneys eliminated about 90% of total radioactivity within 8 hr. In monkeys, DHBE was also excreted mainly by the kidneys, 90% being excreted within 24 hr. Only small amounts were found in the feces of all species.

4628 THE EFFECT OF FUROSEMIDE ON THE FLOW AND COMPOSITION OF BILE IN THE DOG. (Eng.)

Manny, J.; Krausz, M.; Rabinovici, N. (Hadassah Univ. Hosp., Jerusalem, Israel). *Surg. Gynecol. Obstet.* 144(5):721-726; 1977.

The effect of furosemide, a potent inhibitor of active sodium transport, on the amount and composition of bile was studied in six dogs. Furosemide (10 mg/kg) was injected i.v. into anesthetized dogs with a common bile duct fistula. In all dogs, a 2.5-fold increase in bile flow was observed concomitant with a 15-fold increase in urinary output. The amount of bile flow decreased gradually and returned to control levels 60-75 min after furosemide injection. The choleretic effect was associated with a high increase in sodium, chloride, and bicarbonate anions and with a smaller increase in potassium, phosphorus, and calcium. The most affected ion was sodium, the value being 760.0 ± 4.3 μEq before control and 1,675.0 ± 19.3 μEq 30 min after the injection. The total amount of bilirubin, alkaline phosphatase, and cholesterol was not significantly affected, while the calculated output of potassium, calcium, and phosphorus increased. The results indicate that inhibition of sodium reabsorption by furosemide simultaneously affects the liver and kidneys and that the increase in electrolyte solution is most likely caused by the inhibition of sodium reabsorption in the ductuli. Furosemide may also interfere with the sodium mediated secretory fraction at the canalicular level, but the predominant factor determining the increase in bile flow and electrolytes is inhibition of sodium reabsorption in the biliary ducts and ductuli.

4629 EXPERIMENTAL HEPATOBILIARY TOXICITY OF LITHOCHOLIC ACID: EARLY ULTRASTRUCTURAL CHANGES OF HEPATOCYTES. (Fre.)

Grimaud, J. A.; Peyrol, S.; Paliard, P.; Vachon, A. (Institut Pasteur de Lyon, 77, rue Pasteur, F-69365 Lyon Cedex 2, France). *Gastroenterol. Clin. Biol.* 1(4):353-360; 1977.

The chronic administration of lithocholic acid leads to a perilobular fibrosis and intrahepatic cholestasis. To discover the initial changes induced by this acid, rabbits were given 150 mg of lithocholic acid daily, p.o., and sacrificed after 10, 20, and 30 days. Electron microscopic studies of their hepatocytes revealed no changes after 10 days and an increase in smooth endoplasmic reticulum after 20 days. After 30 days, there was a further proliferation of the smooth endoplasmic reticulum, together with the appearance of dense intracytoplasmic bodies and modifications of the biliary poles, which contained a clear peribiliary zone with very few microfilaments. These findings show that the initial lesions induced by the chronic administration of lithocholic acid are localized on the canalicular membrane of hepatocytes.

4630 THE PHARMACOLOGY OF PIPROZOLINE. (Ger.)

Herrmann, M.; Birkenmayer, E.; Ganser, V.; Heldt, W.; Steinbrecher, W. (Godecke AG, Mooswaldallee, 7800 Freiburg/Breisgau, W. Germany). *Arzneim. Forsch.* 27(2b):467-475; 1977.

The general toxicological and pharmacological characteristics of the new choleretic drug piprozoline were studied in animals. The acute intragastric LD_{50} was 1,310 mg/kg in male NMRI mice, 1,070 mg/kg in female mice, 3,256 mg/kg in male SIV-50 rats, and 3,640 mg/kg in female rats. Toxic symptoms (ataxia, sedation, intensified respiration, salivation, and tremors) appeared at doses considerably higher than 400 mg/kg. Piprozoline consistently produced a markedly dose-dependent, long-lasting choleretic effect in mice, rats, cats, and dogs that was higher than that of reference drugs (1-phenyl-1-propanol, 1-phenyl-1-hydroxy-n-pentane, and Silymarin). Intraduodenal doses of 25, 50, and 200 mg/kg to rats enhanced bile secretion by 40%, 90%, and 150%, resp. Prophylactically administered piprozoline significantly inhibited liver damage in rats, demonstrated by the significant reduction of hexobarbital-induced sleep in rats with carbon tetrachloride- and galactosamine-induced liver damage and in mice with amanitine-induced liver damage. The pharmacological properties of piprozoline did not interfere with its use as a choleretic. Piprozoline can be considered a true cholepoietic agent in that it increases bile fluid and solids.

4631 STUDIES OF THE INFLUENCE OF PIPROZOLINE ON THE RAT LIVER MICROSOMAL ENZYME SYSTEM. (Ger.)

Friedrich, G.; Vollmer, K. O. (Godecke AG, Abteilung Biochemie, Mooswaldallee, 7800 Freiburg/Breisgau, W. Germany). *Arzneim. Forsch.* 27(2b):517-519; 1977.

The effects of piprozoline on hepatic microsomal enzymes were studied in male SIV-50 and Wistar rats. Piprozoline significantly prolonged hexobarbital-induced sleep (from 20.2 ± 6.8 to 36.7 ± 14.3 min, $p<0.002$), but only when administered in a high dose of 500 mg/kg intragastrically (i.g.) Administration of 3 x 250 mg/kg/day on 4 consecutive days reduced hexobarbital-induced sleep (19.5 ± 3.4 to 13.5 ± 4.6 min, $p<0.005$), indicative of a weak inductive action on the oxidative enzyme system. *In vitro* studies of the microsomal enzyme systems were performed with Wistar rats 15 or 40 hr after the administration of 2 x 250 mg/kg/day i.g. on 4 or 5 consecutive days. The group sacrificed 15 hr after the 5-day treatment showed a significant decrease in aminopyrine *N*-demethylating enzymes (from 11.73 ± 1.6 to 9.85 ± 0.89 mol/mg/min, $p<0.03$) and significant increases in *p*-nitroanisol *O*-demethylating enzymes (4.14 ± 0.57 to 6.93 ± 1.2 mol/mg/min, $p<0.0001$), NADPH-dependent cytochrome-C reductase (55.95 ± 8.7 to 66.27 ± 4.1 mol/mg/min, $p<0.03$), chloramphenicol glucuronidase (1.29 ± 0.14 to 2.40 ± 0.31 mol/mg/min, $p<0.0001$), and *p*-nitrophenol glucuronidase (63.51 ± 16.1 to 102.63 ± 12.2 mol/mg/min, $p<0.002$). Liver weight was increased by 12% compared with controls. The results suggest that piprozoline does not induce the mixed-function oxidase system in man, even after long-term administration.

4632 SUBCELLULAR REACTIONS TO INJURY. I. ULTRASTRUCTURAL AND BIOCHEMICAL INVESTIGATIONS ON THE HEPATIC CELLULAR DAMAGE PRODUCED BY HAEMORRHAGIC SHOCK IN DOGS. (Eng.) Russo, M. A.; Conforti, A.; Bellavia, A.; Grassetti, F. (Pennsylvania Muscle Inst., Univ. Pennsylvania, 51 North 39th St., Philadelphia, PA 19104). *J. Pathol.* 121(2):107-112; 1977.

The morphological and biochemical-biophysical alterations occurring in hepatocytes following hemorrhagic shock were studied in 10 dogs. Hemorrhagic shock was produced by progressive bleeding through an angiographic catheter passed via the femoral vein into the inferior vena cava. The bleeding occurred in two steps. In the first step, a mean arterial blood pressure of 60 mm Hg was obtained in 25 min. This pressure was maintained, with a total loss of blood of 14 ± 3 cm^3/kg by the end of the 1st hr. For the second step, bleeding was accelerated to attain a mean arterial blood pressure of 45 mm Hg by the 20th min of the 2nd hr; this pressure was maintained for the last 40 min. Sublethal hepatocyte damage was evident in the 1st hr of bleeding. Electron microscopy revealed that the most prominent changes occurred in the mitochondria. High-amplitude swelling, fragmentation of the cristae, irregular density of the matrix, and diminution or disappearance of the granules were seen. The rough endoplasmic reticulum showed fragmentation, degranulation, and apparent formation of membranous whorls and clusters of vesicles. Autophagocytic vacuoles containing glycogen, membranes, and other cellular components were seen. Double membrane whorls at the biliary pole of the cell and disappearance of the microvilli were also seen after 1 hr. After the 2nd hr of bleeding, cariolysis and dispersion of the nucleolar components were observed in the hepatocyte nucleus, and vacuolization and other damage was seen in the cytoplasm. The blood pO_2 and O_2 consumption decreased significantly during bleeding, while the blood glucose and lactate concentrations rose. The lactate/pyruvate ratio increased in parallel with the O_2 level of the blood, being 11.6 before bleeding, 19.4 after 1 hr, and 32.0 after 2 hr. The results indicate that experimentally induced hemorrhagic shock produces cellular damage by three main mechanisms: anoxia, hemodynamic alterations, and metabolite deprivation.

4633 EFFECT OF d-LIMONENE AND RELATED COMPOUNDS ON BILE FLOW AND BILIARY LIPID COMPOSITION IN RATS AND DOGS. (Eng.) Kodama, R.; Inoue, H.; Noda, K.; Ide, H.; Yamamoto, H.; Yoshihara, S.; *et al.* (Hisamitsu Pharmaceutical Co. Inc., Tosu, Saga, Japan). *Life Sci.* 19(10):1559-1568; 1976.

The effect of d-limonene and related compounds on bile flow was investigated to assess their potential as choleretic agents. d-Limonene enhanc bile flow in rats and dogs with a dose-response correlation. Three to four hours after the admini tration of 850 mg/kg d-limonene, bile flow increas to about 160% ($p<0.01$) of the control value of 79 ± 14 μl (this latter value represents a 1-hr colle tion just prior to drug administration). The chol eretic activity of the hydroxyl metabolites of d-limonene e.g., *p*-mentha-1,8-dien-10-ol, *p*-menth ene-8,9-diol, and *p*-mentha-1,8-dien-6-ol was much higher ($p<0.01$) than that of d-limonene. The ran of bile flow for these compounds (250 mg/kg) was 170-230% of the controls (788 ± 24 μl/hr); *p*-ment 1-ene-8,9-diol was the most effective. The choleretic activities of esters of *p*-menth-1-ene-8,9-diol with acetic, propionic, and nicotinic acids (1.47 mmol/kg, corresponding to 250 mg/kg of orig inal diol) enhanced bile flow, but to a lesser ex tent than the original diol in rats ($p<0.01$) and to a higher extent than the original diol in dogs d-Limonene decreased the ratio of bile salts and phospholipids to cholesterol ($p<0.05$), whereas *p*-menth-1-ene-8,9-diol increased it ($p<0.05$). It is suggested that *p*-menth-1-ene-8,9-diol may b useful both as a drug for the prevention and treatment of human cholelithiasis and as a choler tic agent.

4634 FACTORS AFFECTING LIVER LIPID CONTENT I PYRIDOXINE-DEFICIENT RATS. I. DIETARY PROTEIN LEVELS. (Eng.) Suzuki, K.; Nakamura, T. Fujita, M.; Iwami, T.; Abe, M.; Okada, M. (Sch. Medicine, Tokushima Univ., Tokushima, Japan). *J. Nutr. Sci. Vitaminol.* 22(4):291-298; 1976.

The effects of choline fortification and various dietary protein levels on liver lipid content in pyridoxine-deficient male Wistar rats were invest gated. When rats were fed a 70% casein, pyridox deficient diet fortified with 4 g/kg choline ins of the standard 2 g/kg choline, the liver lipid content was not decreased (7.18 ± 1.13% and 7.22 0.67% for rats receiving 4 g/kg and 2 g/kg choli resp.). Reducing the protein level in pyridoxin deficient diets decreased the extent of liver li accumulation (7% versus 5% liver lipid content i rats fed 70% or 10-30% casein diets, resp.). A highly negative correlation ($p<0.05$) was observe between liver lipid content and liver glutamic pyruvic transaminase activity, indicating that t fatty infiltration of the liver may be intimatel related to the pyridoxine deficiency state. In studies of the time course of fatty liver develo ment in rats fed 70% casein diets with (controls or without pyridoxine, rats deficient in pyridox showed a rise in liver lipid content within 1 we it was increased to 2.3 times that of the pair-f controls at 3 weeks. Control rats maintained no mal lipid levels. When rats were fed a 20% case pyridoxine-free diet or a 70% casein, pyridoxine-supplemented diet for 2 days following a 70% casein, pyridoxine-free diet for 19 days, liver lipid content was decreased in both groups from about 10% to about 6%. Control rats fed the 70% casein, pyridoxine-free diet continuously showed a further increase in lipid content (reaching about 11% by the 21st day of feeding). Although the liver lipid content was decreased in rats fed the 70% casein, pyridoxine-supplemented diet, significant liver enlargement was observed. These results indicate that pyridoxine deficiency may not be directly responsible for liver lipid accumulation. Increased carbohydrate intake along with the attendant change in hormonal conditions may be contributing factors. At present, it is only possible to say that the fatty infiltration of liver is due to a disturbance of homeostasis in the regulatory system of hepatic lipid metabolism under severe pyridoxine deficiency.

4635 DOSE-DEPENDENT DISPOSITION OF THE CARDIAC GLYCOSIDES OUBAIN AND K-STROPHANTHOSIDE IN RAT LIVER. CONSEQUENCES FOR (Na^+, K^+)-ATPase INHIBITION AT SINUSOIDAL AND CANALICULAR SITES [Abstract]. SECRETION AND METABOLISM

Intestine

675 COMPENSATION BY THE RESIDUAL INTESTINE AFTER INTESTINAL RESECTION IN THE RAT. I. INFLUENCE OF POSTOPERATIVE TIME INTERVAL. (Eng.) Hanson, W. R.; Osborne, J. W.; Sharp, J. G. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL 60439). *Gastroenterology* 72(4):701-705; 1977.

The sequence of events comprising the early response of the residual intestine to 70% resection of the combined jejunum and ileum was investigated to gain further information on the mechanisms involved. Animals were killed at 2, 4, 6, 8, and 12 postoperative days. Marked increases in DNA synthesis (expressed as disintegrations/min/crypt), cells per crypt column, labeled cells per crypt column, thickness of intestinal wall components, and cells per villus column were apparent as early as 2 to 4 postoperative days. By 12 days, the values had reached the 30-day postoperative levels found in earlier experiments, indicating that a new steady state had already been reached. Jejunal and ileal crypts responded in almost identical ways during the first 12 days with their sizes increasing to about 150% of control values. However, although jejunal villus cell counts increased to 125% of controls, the ileal villus cell counts increased to 180% of controls, indicating that the sizes of the two crypt and villus epithelial cell populations are independently controlled.

4676 LYMPHOID CELLS OF INTESTINAL MUCOSA POSSESSING BOTH KAPPA AND LAMBDA SPECIFICITIES IN NORMAL SUBJECTS. (Fre.) Hartmann, L.; Liacopoulos, P. (Institut biomedical des Cordeliers 15, rue de l'Ecole de Medecine, 75270 Paris Cedex 06, France). *C. R. Soc. Biol. (Paris)* 284(10):863-866; 1977.

Lymphoid cells possessing both kappa and lambda specificities were observed in the intestinal mucosa of three normal subjects. Intestinal mucosa biopsies were taken by means of a Debray tube and subjected to fluorescent and immunofluorescent studies. All three samples showed a particular number of bipotential cells: the total cell population comprised of kappa + lambda cells in the three samples was 8, 21, and 46% or 3,100, 7,000, and 30,500 cells/μl. The percentage of kappa cells comprised 15, 44, and 73% of the total cell populations, whereas lambda cells accounted for 6, 39, and 48% of the total cell population in the three samples. This variability in lymphoid cells seems to be characteristic and may reflect the high activity of the immune system in the small intestine.

4677 FREE ENDOGENOUS AMINO ACIDS IN PERFUSED RAT INTESTINE. (Spa.) Otero, M. A.; Mataix, F. J.; Varela, G. (Departamento de Nutricion, Facultad de Veterinaria, Ciudad Universitaria, Madrid-3, Spain). *Rev. Esp. Fisiol.* 32(1):47-52; 1976.

Levels of endogenous free amino acids were measured in rat small intestine during saline and glutamic acid perfusions; the contribution of biliary and pancreatic secretions to these amino acid levels was determined by ligating choledochol and pancreatic ducts to the perfused intestine. In 50 rats in which pancreatic secretions were excluded, perfused material contained only trace amino acids, indicating that the major contribution to the free amino acid levels in the intestine is pancreatic secretion. Male Wistar rats (250-300 g) were fasted for 48 hr, anesthetized with sodium pentobarbital
(50 mg/100 g body weight) and intestinally perfuse
with 20 ml sodium chloride (9%) or L-glutamic acid
(0.5 and 1.0 mM in saline) at a rate of 13 ml/hr.
Levels of essential amino acids (threonine, valine
isoleucine, phenylalanine, lysine, and histidine)
were highest with saline perfusion (11.22 ± 0.84
μmol/20 ml perfusate) and decreased with increasin
glutamic acid level (8.08 ± 0.54 and 6.72 ± 0.60
μmol/20 ml perfusate for 0.5 and 1.0 mM glutamic
acid, resp.). Free methionine was not found in a
preciable amounts. Glutamic acid in the perfusat
did not decrease levels of nonessential amino aci
as markedly as it did the levels of essential ami
acids.

4678 INTESTINAL ENZYMES [sic] ACTIVITIES IN
ISOLATED VILLUS AND CRYPT CELLS DURING
POSTNATAL DEVELOPMENT OF THE RAT. (Eng.) Raul,
Simon, P.; Kedinger, M.; Haffen, K. (Unite 61 INS
Avenue Moliere, F-67200 Strasbourg-Hautepierre,
France). *Cell Tissue Res.* 176(2):167-178; 1977.

The developmental pattern of various intestinal
enzyme activities was studied in villus and crypt
cells of normal Wistar rats from 5 days to 8 week
after birth. Alkaline phosphatase and enterokina
activities were always located in the upper villu
zone during postnatal development. Enterokinase
activity was higher in the upper villus cells dur
the 3rd week of life than after this period. Ami
peptidase activity was located in the crypt cells
during the 1st week. Its maximum activity remain
in this area until the 3rd week. At this time,
sucrase activity appeared in the crypt cells. Am
peptidase and sucrase activities rose to the vill
zone during the 4th week. Amylase activity was
detected along the entire crypt-villus axis 5 day
after birth (8 mU/mg protein). Its activity in t
crypt cells reached a maximum at the end of the
1st week and in the upper villus cells, after the
4th week. In contrast with the other enzymes stu
almost all amylase activity was soluble in the
youngest animals, whereas at weaning, most of the
activity appeared in a particulate form in the
villus cells. In the crypt cells, the ratio betw
particulate and soluble form remained unchanged
until the adult stage.

4679 PHOSPHOLIPASE ACTIVITY OF RAT INTESTINE
MODE OF ACTION. (Fre.) Bonnefis, M. J
Rey, G.; Thouvenot, J. P.; Douste-Blazy, L. (Hopi
Purpan, 31052 Toulouse-Cedex, France). *Biochemie*
59(4):355-361; 1977.

Phospholipase (PP) activities of rat intestinal m
cosa homogenates were determined from radioactive
labeled lysophosphadidylcholines (LYS)-^{14}C and
phosphatidylcholines (PH)-^{3}H-^{14}C. The effects of
pH and the duration of incubation on PP activitie
were studied. A study of PP activities with a
mixture of 1-acyl-2-lineoleyl-[1-^{14}C]-glycero-3-
phosphorylcholine and 1-palmityl-[9,10-^{3}H$_2$]-2-acy
glycero-3-phosphorylcholine showed that between p
6.5 and 7.0 both fatty acids (palmitic and linoleic acids) were liberated simultaneously withou
the formation of lyso derivatives. The liberati

of linoleic acid remained constant between pH 7.5 and 9.5 while the liberation of palmitic acid decreased rapidly as the pH was raised. LYS activity on 1-acyl-glycero-3-phosphorylcholine-^{14}C was optimum at pH 6.5. Thus, at pH 6.5 a PP-B activity occurs, between pH 6.5 and 9.0 all activities are in a decreasing phase, and at pH 9.0 only a PP-A$_2$ activity exists. Under these conditions it seems that the PP-B activity found at pH 6.5 can be considered as a result of an A$_2$ activity. The specific activity of lysophospholipase was five times greater than that of PP-type B. Tests with the addition of sodium deoxycholate and an excess of LYS also showed that the total PP activities of rat intestinal mucosa results from a PP-A$_2$ and a LYS-A$_1$ activity.

4680 ESTEROLYTIC ACTIVITIES OF RAT INTESTINAL MUCOSA. 2. PURIFICATION AND PROPERTIES OF A GLYCEROL-ESTER HYDROLASE.

(Eng.) Fernandez-Lopez, V.; Serrero, G.; Negrel, R.; Ailhaud, G. (Departamento di Catalisis, Consejo Superior de Investigaciones Cientificas, Serrano 119, Madrid-6, Spain). *Biochem. Eur. J.* 71(1):259-270; 1976.

The physical properties and activities of a glycerol-ester hydrolase (GEH) from the mucosal scrapings of rat jejunum were examined to define a possible role for the enzyme in lipid degradation. The enzyme was purified by chromatography on carboxyhexanoyl-Sepharose-glyceryl dioctanoate and by gel electrophoresis. A single band with a molecular weight of 68,000 was isolated. The GEH was most active against glyceryl tributyrate at pH 8.0-8.5, with an activation energy of 8.7 kcal/mol (36.4 kjoules/mol). Its substrate specificity is mainly directed against glycerol esters and primary monoalcohols. The enzyme is similar to liver esterase and pancreatic lipase in its substrate specificities, probably occupying an intermediary position between the two. Similarly to pancreatic lipase but not to liver esterase, GEH, was inhibited by bile salts. However, inhibition of GEH was only partial under physiological concentrations of bile salts, and these salts do not occur in the mucosal cells, where the enzyme is frequently located. GEH was stable between pH 4.5-9.0, which means that it probably remains at least partially active *in vivo*. It was concluded that GEH may, either intra- or extracellulary, complement the role of pancreatic lipase in degrading short- and medium-chain triglycerides.

4681 ESTIMATION OF FAT ABSORPTION FROM SINGLE FECAL SPECIMENS USING ^{131}I-TRIOLEIN AND ^{75}Se-TRIETHER. A STUDY IN RATS WITH AND WITHOUT INDUCED STEATORRHEA.

(Eng.) Hoving, J.; Wilson, J. H. P.; Valkema, A. J.; Woldring, M. G. (Univ. Hosp., Groningen, Netherlands). *Gastroenterology* 72(3):406-412; 1977.

The simultaneous use of ^{131}I-triolein and ^{75}Se-triether in a single p.o. dose to estimate fat absorption from incomplete fecal collections was tested in rats with and without steatorrhea induced by biliary fistula or with intestinal ischemia. The total fecal recoveries in normal rats of ^{75}Se and ^{3}H were 98.8 ± 1.8 and 86.8 ± 9.0%, resp. The results in normal rats showed that analysis of single stool samples allows a valid estimate of fat absorption as defined by the balance study based on the total fecal recovery of ^{131}I. However, in normal rats with poor absorption, the absorption values from successively excreted stools showed a tendency to increase. The rats with biliary fistula absorbed the intragastric dose of fat to a considerably lower extent as compared with the controls. No significant difference was observed between the absorption of ^{131}I-triolein and ^{14}C-triether, the respective values being 37.6 ± 7.8 and 38.5 ± 14.0%. The absorption values from successively excreted stools in these animals tended to increase. No evidence of different intestinal transit rates of test fat and marker was observed in bile-diverted rats, suggesting that the observed inconsistency in fat absorption values from different stool specimens reflects intraprandial differences in the absorption of fat. The studies on rats with intestinal ischemia did not support the suggestion that separation of fat and triether occurs if a mucosal defect is involved as the cause of fat malabsorption. It is concluded that this dual isotope technique may be useful in the clinical estimation of fat absorption, as it offers important technical advantages over conventional fat balance studies.

4682 PROTEIN TURNOVER IN INTESTINAL MUCOSAL VILLUS AND CRYPT BRUSH BORDER MEMBRANES.

(Eng.) Alpers, D. H. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *Biochem. Biophys. Res. Commun.* 75(1):130-135; 1977.

Relative turnover rates of intestinal brush border proteins were studied by a double-label technique. Brush borders were isolated from cells at all levels along the villus, and from the crypts. Proteins with large molecular weight (>150,000 daltons) demonstrated more rapid turnover compared with other brush border proteins at all levels along the villus. This rapid turnover was not seen in crypt brush borders. These findings support the concept of protein turnover in intestinal brush borders, and demonstrate differences between the proteins in rapidly growing crypt cells. and in non-growing villus cells.

4683 EFFECT OF ALCOHOL ON THE RELEASE OF SECRETIN AND PANCREATIC SECRETION.

(Eng.) Llanos, O. L.; Swierczek, J. S.; Teichmann, R. K.; Rayford, P. L.; Thompson, J. C. (Universidad Catolica de Chile, Santiago, Chile). *Surgery* 81(6):661-667; 1977.

The effect of alcohol on the release of secretin was studied in 21 human subjects by radioimmunoassay and in dogs and cats by radioimmunoassay and bioassay (pancreatic secretion of water and bicarbonate). In man, plasma secretin levels increased significantly from a basal level of 121 ± 14 to 164 ± 24 pg/ml at 60 min after p.o. ingestion of 40% alcohol (60 ml). The intraduodenal administration of alcohol in man, dogs, and cats did not release secretin or affect pancreatic water and bicarbonate secretion in dogs and cats, but pancreatic protein output was increased moderately in these two species. Plasma gastrin levels rose significantly from a basal level of 52 ± 4 to 64 ±3 pg/ml after ingestion of alcohol in man and from 33 ± 5 to 51 ± 8 pg/ml after administration of alcohol into the stomach of dogs. Administration of alcohol into the duodenum in man, dogs, and cats did not release gastrin. Alcohol probably does not release secretin directly. The mechanism of release of secretin in man is unknown, but it clearly involves the stomach and may be mediated via the release of gastric acid.

4684 EFFECT OF CAFFEINE ON THE HUMAN SMALL INTESTINE. (Eng.) Wald, A.; Back, C.; Bayless, T. M. (Dept. Medicine, Johns Hopkins Univ. Sch. Medicine, Baltimore, MD 21205). *Gastroenterology* 71(5):738-742; 1976.

The influence of caffeine on net secretion and fluid transit time in the human small intestine was studied to relate normal levels of caffeine consumption to possible laxative or diarrheal effects. Eleven healthy volunteers who had no previous history of diarrhea associated with caffeine ingestion were chosen. Caffeine was administered p.o. or through a triple lumen tube into the jejunum in a 100-ml saline solution containing polyethylene glycol. Transit times were estimated by determining the dilution curve of an injected dye. Both oral and direct jejunal administration of caffeine in 75- to 300-mg doses resulted in net secretion of fluid into the jejunal and ileal lumens within 15 and 35 min, resp. The basal jejunal absorption rate of 0.5 ml/cm/hr was reversed to a net secretion rate of 6.0 ± 2.2 ml/cm/hr in five studies ($p<0.01$). The delayed onset of ileal secretion was correlated with transit time of the caffeine bolus and not with plasma caffeine levels. Fluid transit time was either not affected or was slightly prolonged with repeated injections of caffeine. This study confirms the hypersecretory effects of caffeine on the small intestine observed previously in animals. The fact that fluid transit time was unaffected in the volunteer group may be due to the smooth muscle relaxant effect of caffeine on the intestine, thereby increasing its capacity. A possible relationship between caffeine ingestion and functional diarrhea in some individuals is discussed.

4685 COMPENSATORY POSTRESECTIONAL HYPERPLASIA AND STARVATION ATROPHY IN SMALL BOWEL: DISSOCIATION FROM ENDOGENOUS GASTRIN LEVELS. (Eng.) Oscarson, J. E. A.; Veen, H. F.; Williamson, R. C. N.; Chir, B.; Ross, J. S.; Malt, R. A. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 72(5):890-895; 1977.

Because exogenous gastrin has been implicated as a tropic hormone for mucosal cells of the intestinal tract and as a regulator of mucosal growth, the effects of 23-fold variations of serum gastrin produced by various gastric operations were studied in Sprague-Dawley rats. The gastric operations included pyloroplasty, vagotomy and pyloroplasty, antrectomy, and fundectomy. Animals that had undergone one of these operations were randomly allocated
to have jejunal resection or sham operation. Gas-
trin levels for each operation were consistent, i
respective of transection (sham-operation) or re-
section of the gut. Despite increases of 35% to
82% in the amount of RNA in mid-small bowel mucos
2 days after jejunal resection, there was no cor-
relation with the level of serum gastrin. The DN
content of the mid-small bowel increased 35% to 5
in normal rats and after pyloroplasty, vagotomy a
pyloroplasty, and antrectomy, but not after funde
tomy. Increases in the amount of radioactivity i
mid-small bowel mucosa after jejunectomy were pre
ent after all operations but vagotomy-pyloroplast
these increases ranged from 69% to 146%, but did
not correlate with serum gastrin levels. Signif-
icant increases in the specific activity of DNA
in normal rats and in rats after pyloroplasty and
fundectomy did not correlate with gastrin levels.
The gastric operations changed the serum gastrin
level without affecting villus height or crypt
depth, and resections increased height and depth
without affecting serum gastrin. High endogenous
concentrations of serum gastrin did not prevent
loss of RNA and DNA during starvation and did not
affect DNA specific activity. Tropic effects dis
to the duodenum produced by exogenous gastrin and
pentagastrin may be results of supranormal levels
of these compounds.

4686 INTESTINAL MUCOSA IN RATS WITH IRON DEF
CIENCY ANEMIA. (Fre.) Salazar de Sous
J.; Bray Pinheiro, J.; Fernanda Torgal Garcia, M.
Viginia Rebocho Pais, M.; Nunes, V. (Clinique
pediatrique, Hopital de Santa Maria, Lisbon, Port
gal). *Helv. Paediatr. Acta* 31(2):167-171; 1976.

The effects of iron deficiency on the rat intest
mucosa were studied. Two groups of nine rats eac
received either milk supplemented (controls) wit
Fe (0.5 mg/day) and Cu (0.05 mg/day) or unsupple-
mented milk for 2 months. They were then sacrif
for hematological and biochemical evaluation. T
appearance of the gastric and jejunal mucosa was
normal in both groups. However, animals that di
not receive Fe or Cu had very marked anemia, and
epithelial cell height was significantly higher
in these animals compared with controls ($p<0.001$
The relationship between Fe deficiency and struc
alterations of the intestinal mucosa in children
has not been elucidated.

GENERAL

4700 COMPARISON OF VASCULAR EFFECTS OF GASTROINTESTINAL HORMONES ON VARIOUS ORGANS. (Eng.) Chou, C. C.; Hsieh, C. P.; Dabney, J. M. (Dept. Physiology, Michigan State Univ., East Lansing, MI 48824). *Am. J. Physiol.* 232(2):H103-H109; 1977.

The vascular effects of raising the local arterial concentrations of pentagastrin (2-1,500 ng/ml), secretin (0.2-150 mU/ml), and cholecystokinin (0.2-150 mU/ml) in the duodenum, jejunum, heart, kidney, forelimb, spleen, and the skin and muscle of the forelimb were studied in 54 anesthetized dogs. Secretin produced similar vasodilation in all organs. The minimal increment in local blood secretin concentration for vasodilation (concentration requirement) was 7-32 mU/ml. Pentagastrin produced vasodilation only in the duodenum and jejunum, and the concentration requirement was 25-50 ng/ml. The vascular resistance of the forelimb, skin, or muscle was not affected by cholecystokinin. In the heart, kidney, and spleen, cholecystokinin produced vasodilation but the concentration requirement was above 21-33 mU/ml. In contrast, vasodilation in the duodenum and jejunum appeared when cholecystokinin concentration was increased by only 2.5 mU/ml. Almost all its vasodilating effect occurred below an increment of 10 mU/ml. Comparison of these data with the reported cardiovascular adjustments and blood concentration of gastrointestinal hormones following a meal suggests that cholecystokinin may contribute to postprandial intestinal hyperemia.

4701 ENKEPHALIN-LIKE IMMUNOREACTIVITY IN THE HUMAN GASTROINTESTINAL TRACT.

(Eng.) Polak, J. M.; Bloom, S. R.; Sullivan, S. N.; Facer, P.; Pearse, A. G. E. (Royal Postgraduate Medical Sch., Hammersmith Hosp., London W12 OHS, England). *Lancet* 1(8019):972-974; 1977.

Samples of human gastrointestinal tract (gastric body and antrum, duodenum, jejunum, ileum, colon, pancreas, gallbladder, cystic ducts, and bile duct) were examined immunocytochemically for the presence of peptides with opiate-like actions. Enkephalin immunoreactivity was detected in high concentrations in the gastrointestinal tract; the largest amount was found in the antral mucosa (79 ng/g), with lesser amounts in the upper small intestine. In the antrum, approximately equal amounts were found in the mucosa as were extractable from the rest of the stomach wall. Enkephalin was not detected in the fundic mucosa, and the larger endorphin species were not detected anywhere in the gut. Numerous endocrine cells stained specifically with antibodies to *met*-enkephalin in the midzone of the antral mucosa. Enkephalin cells appeared to correspond to the antral gastrin cells but not to the somatostatin or other cells in the same region. Nerve fibers of the myenteric plexus of the gallbladder cystic duct wall and lower intestine were also stained with antibodies to *met*-enkephalin. Gastrointestinal physiology appears to be partly regulated by locally acting hormones, and enkephalin may be one of these. The established effects of morphine on the alimentary tract provide a clue to the possible physiological role of enkephalin.

4702 GASTROINTESTINAL ANTIBODY RESPONSES IN AXENIC MICE TO TOPICALLY ADMINISTERED **Escherichia coli.**

(Eng.) Ebersole, J. L.; Molinari, J. A. (Forsyth Dental Center, Boston, MA 02115). *Infect. Immun.* 16(3):938-946; 1977.

Studies were carried out to determine whether the topical administration of nonviable *Escherichia coli* was capable of eliciting a gastrointestinal humoral immune response in axenic mice. In addition, the kinetics, specificity, and classes of antibodies produced in the intestinal secretions after p.o. sensitization were examined. Axenic animals received nonviable *E. coli* O111:B4 by topical application into the oral cavity. IgA, IgG1, and IgG2 were detected in the gastrointestinal secretions, with an apparent gradation in stability (IgA>IgG1>IgG2). Specific antibodies (IgA and IgG) to both the somatic and the flagellar antigens of *E. coli* were demonstrated. The time-
course of the responses to the polysaccharide anc
protein antigens suggested that a secondary respo
to lipolysaccharide was being observed in the se-
cretions. Examination of the autoclaved diet fec
to the germfree animals indicated the presence of
antigenically intact polysaccharide materials (i
lipopolysaccharides), whereas antigenic bacterial
proteins were uniformly undetectable. Therefore
endotoxin in the diet was apparently causing a
primary type of sensitization in the mice, wherea
the active p.o. immunization regimen induced a
secondary antibacterial response in the secretion

4703 REDISTRIBUTION OF CANINE SPLANCHNIC BL
FLOW FOLLOWING NORMOTENSIVE HEMORRHAGE

(Eng.) Kauffman, G. L., Jr.; D'Alecy, L. G. (Uni
Michigan Medical Center, Ann Arbor, MI 48109).
Surg. Res. 22(5):580-584; 1977.

Changes in splanchnic blood blow were studied in
unanesthetized dogs subjected to normotensive her
orrhage to explain the protection of the gastric
antral mucosa from stress-induced ischemic damage
Gastric mucosal, duodenal, and pancreatic blood
flow was measured in 10 dogs using the radioacti
microsphere technique. Twenty percent of the cal
culated blood volume was withdrawn over a 30-min
period in five dogs. Any animal whose mean arter
ial blood pressure fell more than 10 mm Hg follow
hemorrhage was excluded. Following hemorrhage,
significant reduction in blood flow affected the
gastric body mucosa (-62.3%), duodenum (-46.9%),
and pancreas (-63.7%). No significant blood flow
reduction occurred in the gastric antral mucosa.
Mucosal blood flow reduction after hemorrhage was
significantly greater in the cardia (-65%) than
the preantral regions (-59.5%, p=0.047). Gastric
antral blood flow is minimally sensitive to stres
suggesting a basis for the clinical observation
gastric body ulceration with antral sparing.

4704 CHANGES OF UPPER GASTROINTESTINAL BLOO
FLOW AFTER HEMORRHAGE IN RABBITS. (En

Manabe, T.; Suzuki, T.; Honjo, I. (Beth Israel H
and Harvard Medical Sch., 330 Brookline Ave.,
Boston, MA 02215). *Surgery* 81(4):446-452; 1977.

The sequential changes of blood flow patterns in
the esophagus, the lesser and greater curvature
the corpus, the antrum, and the duodenum in expe
mentally induced hemorrhage and blood transfusio
were studied in rabbits. Blood flow was determi
using radioactive microspheres, which were injec
into the left ventricle. Fifteen minutes after
hemorrhage, the cardiac output decreased to 54.1
of control, and the blood flow of the mucosal la
was reduced significantly to 35.4% of the contro
value in the esophagus, 30.5% in the lesser curv
32.9% in the greater curvature, 34.8% in the ant
and 41.9% in the duodenum. The persistent reduc
of mucosal blood flow continued until 60 min aft
hemorrhage. Despite these distribution patterns
mucosal blood flow during hemorrhage, no macrosc
change was seen in any part of the gastrointesti

mucosa. One hour after blood reinfusion, significant increases in mucosal blood flow were found in the lesser curvature (201.9% of the control value), greater curvature (147.5%), esophagus (85.5%), antrum (122.5%), and duodenum (102.9%). In all animals, bleeding erosions about 0.5 cm in diameter had developed in the corpus. Six hours after blood reinfusion, the bleeding from the mucosal foci in the corpus ceased, and the mucosal blood flow returned almost to normal (to 140.7% in the lesser curvature and to 78.1% in the greater curvature). The higher susceptibility of the corpus to hemorrhagic shock may be due to the greater degree of rapid increase of mucosal blood flow occurring in this portion alone after blood transfusion, as well as to its higher vulnerability to ischemia in the hemorrhagic period. The flow patterns in the muscular layer approximately paralleled those in the mucosal layer during hemorrhage and blood transfusion.

4705 SYMPATHETIC NERVOUS CONTROL OF INTRAMURAL BLOOD FLOW IN THE FELINE AND HUMAN INTESTINES. (Eng.) Hulten, L.; Lindhagen, J.; Lundgren, O. (Dept. Surgery II, Univ. Goteborg, Fack, 400 33 Goteborg 33, Sweden). *Gastroenterology* 72(1):41-48; 1977.

The effect of electrical stimulation (8 Hz) of the regional sympathetic vasoconstrictor fibers on total and intramural blood flow in feline and human small and large intestines was studied by an inert-gas-washout technique. The initial response to electrical stimulation in both cat and man was a marked reduction in intestinal blood flow, followed by an increase 3-4 min later. This characteristic flow response, an "autoregulatory escape" phenomenon, levels off at a reduced but steady value around 5 min after the start of stimulation. In the cat, the flow distribution was unchanged. In man, however, vasoconstriction was more pronounced in the muscularis than in the mucosa-submucosa and a larger fraction of the total blood flow was diverted to the mucosa-submucosa. These results are similar to the response patterns observed in the stomach.

4706 STUDIES ON CIRCULATING BLOOD IN ALERT HUMANS AND ANIMALS. II. STUDIES ON MECHANISM OF WATER RESORPTION FROM THE INTESTINE TO THE BLOOD OF THE V. PORTAE IN RATS. (Ger.) Aziz, O.; Sommer, E. (Institut fur Angewandte Physiologie, Philipps-Universitat, Lahnberge, D-3550 Marburg/Lahn, W. Germany). *Res. Exp. Med. (Berl.)* 169(1):45-67; 1976.

The course and volume of intestinal electrolyte concentrations were examined by continuous conductometry of portal venous and aorta blood ultrafiltrates in the rat. Intraduodenal infusion of tap water in rats corresponding to 0.5, 1.0, and 2.0% of body weight led to different reactions in the course and volume of arteriovenous differences (AVD) of electrolytic concentration. The highest AVD (9 mVal/l) was recorded at a water gush of 2.4 ml and a portal flow of 14.5 ml/min, indicating a water flux into the blood of nearly 0.9 ml/min. Permeability changes, for water in the lumen-to-blood and for electrolytes in the blood-to-lumen direction, are considered to be the cause of the above differences. Thirst appears to have an enhancing effect on AVD.

4707 BLOOD FLOW AND OXYGEN CONSUMPTION IN THE FELINE SMALL INTESTINE: RESPONSES TO ARTIFICIAL DISTENSION AND INTESTINAL OBSTRUCTION. (Eng.) Ohman, U. (Karolinska Sjukhuset, Stockholm, Sweden). *Acta Chir. Scand.* 142(4):329-333; 1976.

Relations between blood flow and oxygen consumption were studied in denervated and homologously perfused feline small intestine. Under resting conditions, oxygen uptake was independent of blood flow within rather wide limits, whereas fractional oxygen extraction displayed a highly significant correlation to flow. Upon artificial distension of the bowel, oxygen uptake became a function of blood flow. The results suggest that autoregulation of oxygen uptake may occur. This autoregulation is abolished upon bound distension. The continuing distension of simple intestinal obstruction causes an inability of the bowel wall vasculature to extract and consume the oxygen currently needed, probably a result of disturbed autoregulation of oxygen uptake. An intervening decompression seems to re-establish autoregulation in the obstructed bowel. The results corroborate the previous suggestion that intra-operative decompression of obstructed bowel restores the ability of its capillary circulation to withstand, with retained function, renewed increments of strain and distension.

4708 ONSET OF CELL PROLIFERATION IN THE SHORTENED GUT: GROWTH AFTER SUBTOTAL COLECTOMY. (Eng.) Buchholtz, T. W.; Malamud, D.; Ross, J. S.; Malt, R. A. (Massachusetts General Hosp., Boston, MA 02114). *Surgery* 80(5):601-607; 1976.

Nucleic acid synthesis and morphological changes were studied in the small intestine of colectomized and sham-colectomized Sprague-Dawley rats for 30 days postsurgery. Nucleic acid synthesis dropped during the first 3 postoperative days, but then began to increase to control levels within a week. Compared to sham-colectomized rats, the significant increments in RNA content at 30 days were 22% in the ileum, 20% in the mid-small bowel, and 18% in the jejunum. Increments in DNA content were insignificant in the ileum, 21% in the mid-small bowel, and 12% in the jejunum. However, the absolute increases in RNA and DNA within a length of small intestine from days 3 to 30 postcolectomy were each 90% in the ileum. The morphological changes followed a similar pattern: low villi and shallow crypts appeared during the first week, but higher villi and deeper crypts were observed from the 14th to the 30th day. By the 14th day, cell migration from the crypts to the tips of the villi had increased 56% in the ileum and 28% in the jejunum. It was concluded that subtotal colectomy in the rat stimulates a compensatory effect of increased cell division and nucleic acid synthesis in the small bowel within 2 weeks after the operation.

4709 ILEAL EPITHELIAL CELL MIGRATION AFTER 40% SMALL-BOWEL RESECTION: AUTORADIOGRAPHIC STUDIES IN THE RAT.

(Eng.) McDermott, F. T.; Roudnew, B. (Alfred Hosp., Monash Univ., Melbourne, Australia). *Am. J. Dig. Dis.* 22(7):637-640; 1977.

An autoradiographic investigation with [^{3}H]thymidine of epithelial cell migration 60 days after 40% small bowel resection was carried out in male Sprague-Dawley rats, to examine small bowel adaptation after enterectomy. The mean number of cell positions between the crypt-villus junction and the leading labeled cell 30 hr after injection was increased by 19.4% in the resected group ($p < 0.02$). The mean total number of cells per villus column was increased by 27.8% ($p < 0.002$). Migration rate estimated in cell positions per hour was accelerated by 18.9% ($p < 0.001$) after resection. The 8.1% lengthened life span of villus cells was not statistically significant. The increased number of cells per villus column and unaltered life span of villus cells would facilitate functional adaptation. The causal relationship between the larger villus cell population and accelerated migration after resection and increased crypt cell proliferation is unknown.

4710 ANALYTICAL SUBCELLULAR FRACTIONATION OF JEJUNAL BIOPSY SPECIMENS: METHODOLOGY AND CHARACTERIZATION OF THE ORGANELLES IN NORMAL TISSUE.

(Eng.) Peters, T. J. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12 OHS, England). *Clin. Sci. Mol. Med.* 51(6):557-574; 1976.

Analytical subcellular fractionation of jejunal biopsy specimens (10 mg wet weight) was done in a single-step procedure by isopycnic centrifugation on a continuous sucrose or sorbitol density gradient with the Beaufay automatic zonal rotor. The supernatant (3.5 ml after centrifugation of the homogenate at 800 x *g* for 10 min) was layered over a 30 ml density gradient from 1.05 to 1.28 resting on a 4 ml cushion of density 1.32 and centrifuged at 35,000 rpm for 35 min. All the principal organelles were characterized by their modal equilibrium densities in sucrose gradients: brush borders (density 1.21), peroxisomes (density 1.18), mitochondria (density 1.16), endoplasmic reticulum (density 1.16), and basal lateral membranes (density 1.12). Three distinct populations of lysosomes with different modal densities and enzyme content were shown. The technique is applicable to the study of the physiology or pathology of any organ amenable to biopsy.

4711 EXPERIMENTAL REPRODUCTION OF HIRSCHSPRUNG'S DISEASE BY ACUTE NEUROTOXIC ARTERIAL PERFUSION.

(Spa.) Martinez-Almoyna, R. C.; Claver, M.; Monereo, G. J. (Clinica Infantil "La Paz," Ciudad Sanitaria de la Seguridad Social "La Paz," Madrid, Spain). *Rev. Clin. Esp.* 140(1):19-27; 1976.

Histological lesions of the intramural plexus were produced in 12 cats by regional arterial perfusion of the colon with a neurotoxin (mercuric chloride) Perfusion of the inferior mesenteric artery was initiated with 20-40 cm^3 Tyrode's solution; Tyrode's solution (6 cm^3) plus 0.02 mg% mercuric chloride were then added, and all veins in the perfused area were closed off for 1 hr. Animals were sacrificed 2 days (group I, 1/12 cases), 2-3 weeks (II, 5/12), 4-5 weeks (III, 3/12), or 17 weeks (IV 3/12) after perfusion. Mortality was 25%: 3 cats died from perforation of the colon, all in group I The perfused zone showed colonic dilatation (maxim 15.4 mm, II) or stenosis (6 mm, IV) and decrease i length (minimum, 11.6 cm, II). No small intestina changes were noted. Neuronal changes in Auerbach Meissner plexa were slight in groups I, III, and I and were most pronounced in II; effects included h ganglionism (2/5), cytoplasmic and nuclear vacuoli tion (5/5), nuclear pinocytosis (5/5), and inflamm tory infiltration (5/5). In group II, only one of three animals showed any such change. The authors note that inconsistencies in the results may be du to poor experimental techniques, induction of insu ficient ischemia in the perfused area allowing neuron recovery, or induction of an insufficient level of hypoxia.

4712 GLYCOSIDE-INDUCED INTESTINAL ISCHEMIA. THERAPEUTIC POSSIBILITIES.

(Ger.) Bro mann, G. F.; Mikosch, H.; Mayer, M. (Chirurgische Universitatsklinik, Hugstetter Strasse 55, D-7800 Freiburg, W. Germany). *Med. Klin.* 71(47):2066-20 1977.

Extracardiac glycoside changes were studied by mechanical ventricular massage with the Anstadt-c in dogs. The decrease in mesenteric arterial circulation following administration of strophant (0.05 mg/kg, i.v.) is explained by the direct ext cardiac effect of the glycoside on vascular smoot muscle. Inhibition of Ca-synergistic effect of t glycoside by verapamil (0.5 mg/kg, i.v.) was independent of time of administration (i.e., befo simultaneously with, or after strophanthin). Car glycosides may play an important role in the path physiology of intestinal infarction.

4713 ROLE OF PANCREATIC PROTEASES IN THE PAT GENESIS OF ISCHEMIC ENTEROPATHY.

(Eng. Bounous, G.; Menard, D.; de Medicis, E. (Centre Hospitalier Universitaire, Sherbrooke, Quebec, Ca ada J1H 5N4). *Gastroenterology* 73(1):102-108; 19

The effect of trypsin, chymotrypsin, and elastase upon the loss of brush border proteins after shor term occlusion of the superior mesenteric artery was studied in Wistar rats, and the effect of the same enzymes upon the loss of mucosal DNA and pro teins after long-term mesenteric ischemia was als investigated. After 45 min of ischemia, total br border proteins and activities of sucrase, γ-glut myltransferase (GGTPase), and leucylnapthylamidas (LNAase) in the small bowel decreased by 58, 66, and 67%, resp. ($p<0.001$); these decreases were not influenced by previous inhibition of trypsin and chymotrypsin in the lumen with Aprotinin. Prior intestinal perfusion reduced this loss to 17% for total brush border proteins and 30, 29, and 30% for the activities of sucrase, GGTPase, and LNAase, resp. The potential effect of elastase was estimated by adding a physiological amount of the enzyme to the lumen after complete intestinal perfusion and before ischemia. Under these conditions, elastase induced a 21% loss of total brush border proteins and a 35, 46, and 37% drop in the activities of sucrase, GGTPase, and LNAase, resp. When ischemia was prolonged to 100 min, previous selective inhibition of trypsin and chymotrypsin in the lumen with Aprotinin minimized its effects on loss of mucosal weight, DNA, and proteins. These biochemical data, consistent with the morphological picture, suggest the following theory: in the initial phase of ischemia, factors within the intestinal lumen, especially elastase, contribute substantially to the loss of brush border proteins. After the disappearance of the brush border, in the advanced phase of ischemia, the protection by trypsin-resistant glycoproteins is lost, hence the underlying structures are accessible to the digestive action of trypsin, chymotrypsin, and elastase present along the intestinal wall and lumen.

4714 THE ACTION OF FOOD AND MICROBIAL FLORA OF THE DIGESTIVE TRACT ON THE INTESTINAL POOL AND FECAL EXCRETION OF BILIARY ACIDS IN THE RAT: COMPARATIVE STUDY OF AXENIC, GNOTOXENIC AND HOLOXENIC RATS. (Fre.) Sacquet, E.; Mejean, C.; Leprince, C.; Riottot, M.; Raibaud, R. (Laboratoire des animaux sans germes du C.N.R.S., C.N.R.Z., 78350, Jouy-en-Josas, France). *Ann. Nutr. Alim.* 30:603-617; 1976.

The effects of different diets and microbial flora of the digestive tract on cecum distension and on the intestinal content and fecal excretion of bile acids (BA) in axenic, holoxenic, and gnotoxenic, rat are presented. The bacteria that did not metabolize BA were given to axenic rats by stomach and rectal tube; fecal BA were separated by chromatography. Of the 73 strains of bacteria and one fungus isolated, 27 bacteria and the fungus did not metabolize BA. These strains reduced cecum distension of axenic rats fed a semisynthetic diet (SN: consisting of 22% casein, 9% corn oil, 4.5% mineral salts, 5% cellulose, 58% corn starch) with or without cholesterol (CL). Only partial cecum reduction was seen in rats given a commercial feed (CF: 21% crude protein, 3.5% fats, 5% cellulose). In axenic rats fed SN without CL, the intestinal BA content was twice as high as that of holoxenic rats but fecal BA excretion was slightly lower. Intestinal BA were also raised in axenic and holoxenic rats given CF plus CL. The small intestinal BA content and fecal excretion were greatest in axenic and holoxenic rats fed CF with CL. A study of the composition of the feces showed that SN without CL caused a slight increase of cholic acid, whereas the proportion of cholic acid was much less in the three groups of rats that received a CL diet. Feces from holoxenic rats given a SN with CL showed few changes. However, holoxenic rats fed CF had marked changes in fecal BA. The results suggest that bacteria of the digestive tract exert a nonspecific action on the fecal excretion and intestinal content of BA by reducing cecum distension in axenic rats.

4715 ANTIGEN DEGRADATION IN HUMAN COLON ECOSYSTEMS: HOST'S ABO BLOOD TYPE INFLUENCES ENTERIC BACTERIAL DEGRADATION OF A CELL SURFACE ANTIGEN ON Escherichia coli 086. (Eng.) Cromwell, C. L.; Hoskins, L. C. (Northpoint Medical Group, Ltd., 2388 N. Lake Drive, Milwaukee, WI). *Gastroenterology* 73(1):37-41; 1977.

To determine whether human enteric bacterial enzymes that degrade the oligosaccharide moieties of gut mucin glycoproteins also degrade related heteroglycan antigens on the cell walls of enteric bacteria, the ability of enzymes in fecal extracts and anaerobic fecal cultures to degrade a cell surface antigen on *Escherichia coli* 086 was studied. This antigen is structurally and immunologically similar to oligosaccharides containing human blood group B antigenic determinant α-D-(1-3)-galactopyranosyl moieties. Enzyme activity in fecal extracts and fecal cultures degraded the B-like antigen from the surface of *E. coli* 086, but degradation was slower than degradation of B antigen from salivary mucin glycoproteins, and the rate varied among individual subjects. One determinant of degradation rate was the host's blood type. Fecal extracts and cultures from four of six blood group B secretors caused 94% or greater loss of B-like antigen from the bacteria in 24 hr, but only one fecal extract and no fecal culture from ten group A or O secretors degraded it this rapidly from the cells. A bacterial B-degrading α-galactosidase is probably responsible for loss of antigen from *E. coli* 086 during incubation with fecal extract since galactose was released concurrently from the cells and added galactose inhibited the loss. These results suggest that: (1) cell surface antigens on enteric bacteria may normally be degraded by bacterial enzymes in the human colon, and (2) bacterial enzyme adaptation to blood group antigens in the host's gut mucins enhances degradation of similar structures on enteric bacteria.

4716 GASTRIC CLEARANCE OF GASTRIN DURING ACID SECRETORY RESPONSES TO VAGAL ACTIVATION AND ITS EFFECT ON PERIPHERAL GASTRIN LEVELS. A STUDY ON ANESTHETIZED CATS. (Eng.) Uvnas-Wallenstein, K.; Uvnas, B. (Dept. Pharmacology, Karolinska Institutet, Stockholm, Sweden). *Acta Physiol. Scand.* 97(3):349-356; 1976.

The relationship of peripheral gastrin levels to the amount of gastric secretion was studied in anesthetized cats by electrical stimulation of the vagi. During a series of 15 experiments, peripheral gastrin levels were unchanged or only slightly increased in the presence of a strong secretory response, but peripheral levels were greatly increased when there was only minimal secretion. There was a significant arteriovenous difference in plasma gastrin levels in the corporeal blood during the vagally-stimulated secretory response. This difference might be due to degradation of gastrin in the corpus mucosa, resulting in the lower levels found in the venous blood, or to secretion into the gastric juice. The clearance of gastrin was 104-540 pg/min, large enough to explain the peripheral levels of gastrin observed in the presence or absence of gastric secretion.

4717 FIBRINOLYTIC ACTIVITY OF ADULT RAT LIVER CELLS IN PRIMARY CULTURE AND INHIBITION BY GLUCOCORTICOIDS. (Eng.) Laishes, B. A.; Roberts, E.; Burrowes, C. (Dept. Pathology, Univ. Toronto, Toronto, Ontario, Canada M5S 1A8). *Biochem. Biophys. Res. Commun.* 72(2):462-471; 1976.

The extracellular digestion of fibrin by individual, cultured primary hepatocytes was investigated to correlate morphological changes of viable, non-growing cells with protease secretion and hormonal responsiveness. Liver tissue from adult male Fischer-344 albino rats was digested with collagenase, and suspensions of 10^5 viable cells were plated in Williams E medium in monolayer flasks. Fibrinolytic activity was detected by the appearance of clear plaques in an opaque agar overlayer containing bovine thrombin, bovine fibrinogen, bovine fetal serum, and Williams medium. Fibrinolysis was also quantitated from cell-free supernatants of hepatocytes by their ability to digest ^{125}I-fibrin films. Plaques indicating proteolysis appeared within 3 days, and they were scored for the presence of single cells with rounded or spreading morphology. Single-cell plaques appeared with a frequency of 2.4×10^{-3} per viable cell number, independently of the number of viable cells remaining. All proteolytically active cells were flattened and spread out. Both the occurrence of flattened cells and their proteolytic activities were inhibited almost completely by dexamethasone (10^{-8} to 10^{-6} M) and, to a lesser degree, by hydrocortisone (10^{-4} M). Dexamethasone did not inhibit the actual fibrinolytic reaction. Proteolysis may be intimately related to the morphological changes of normal hepatocytes.

DIAGNOSTIC PROCEDURES

4740 THE DIAGNOSTIC SIGNIFICANCE OF INTESTINAL METAPLASIA IN ENDOSCOPIC GASTRIC BIOPSIES. (Eng.) Johansen, A.; Sikjar, B. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 85(2):240-244; 1977.

The incidence of intestinal metaplasia was determined in gastric biopsy specimens from nondiseased areas of stomachs with proven carcinoma or benign lesions. Although intestinal metaplasia was found more frequently among the 315 biopsies from stomachs with carcinoma than among the 786 biopsies from stomachs with benign disease, this difference was not statistically significant. However, 17% of 82 biopsies from stomachs with carcinoma had extensive intestinal metaplasia, while only 7% of 189 biopsies from stomachs with benign lesions had extensive metaplasia ($p<0.05$). Although intestinal metaplasia seems to be associated with stomach carcinoma, this could not be used for diagnostic purposes.

4741 ULTRASOUND IN THE DIAGNOSIS OF IDIOPATHIC HYPERTROPHIC PYLORIC STENOSIS. (Eng.) Teele, R. L.; Smith, E. H. (Children's Hosp. Medical Center, 300 Longwood Ave., Boston, MA 02115). *N. Engl. J. Med.* 296(20):1149-1150; 1977.

Ultrasound was used in the diagnosis of hypertrophic pyloric stenosis in five babies (aged 5-16 weeks) with vomiting but no palpable tumors. In one patient, the upper gastrointestinal series was typical of idiopathic hypertrophic pyloric stenosis; in one the radiographs were suggestive of this condition; and in three, they were abnormal but not typical. The ultrasonic scans were strikingly similar. Four patients had a mass in the angle formed by the lower portion of the right hepatic lobe and the upper pole of the kidney. A fifth patient had a mass anterior to the spine. In each patient, the mass was round or oval and relatively echolucent, with a central stellate or cleft-like collection of echoes. The average anteroposterior diameter of each mass was 2.3 cm (range 1.8-2.8 cm). Each patient underwent surgery, and in each the diagnosis was confirmed. The ease and safety of ultrasonic examinations make them useful in the diagnosis of idiopathic hypertrophic pyloric stenosis when the tumor is not palpable or when the radiographs are atypical.

4742 AN EVALUATION OF THE DOUBLE CONTRAST BARIUM MEAL (DCBM) AGAINST ENDOSCOPY. (Eng.) Herlinger, H.; Glanville, J. N.; Kreel, L. (St. James' Univ. Hosp., Leeds, England). *Clin. Radiol.* 28(3):307-314; 1977.

The diagnostic accuracy of the double contrast barium meal (DCBM) and of endoscopy were compared in 50 patients. Diagnosis by means of endoscopy was reported to be better than DCBM since the former is backed by histology and cytology, and one is able to make diagnostic use of the color change of the mucosa in certain inflammatory states. The potential accuracy of DCBM was calculated to be 96% of that accorded to fiberendoscopy. DCBM is reported to be somewhat better than endoscopy in the detection of gastric ulcer scars, ulcers hidden by edema and ulcers in the fundal area of the stomach, where as endoscopy was slightly superior in detecting the duodenal lesions, rare lesions of the anterior stom ach wall, and in diagnosis after partial gastrectom Gastrobulbar endoscopy and DCBM were found to be complementary, and the use of both techniques is suggested to achieve maximum diagnostic accuracy.

4743 USE OF BREATH HYDROGEN (H_2) TO QUANTITAT SMALL BOWEL TRANSIT TIME FOLLOWING PARTI GASTRECTOMY. (Eng.) Bond, J. H.; Levitt, M. D. (Veterans Admin. Hosp., 54th St. and 48th Ave. S., Minneapolis, MN 55417). *J. Lab. Clin. Med.* 90(1): 30-36; 1977.

A technique involving the measurement of pulmonary H_2 excretion after the ingestion of lactulose was used to study the relation between small intestina transit time and postgastrectomy diarrhea. Ten postgastrectomy patients with persistent diarrhea had an average small bowel transit time of 35.2 ± 3 min, which was significantly ($p<0.05$) shorter th either that of 10 patients without diarrhea (74.6 ± 5 min) or 40 healthy controls (72.6 ± 5 min). These decreased transit times appeared to be due t rapid gastric emptying rather than to a primary intestinal abnormality, since the transit of lactulose instilled directly into the jejunum was equally rapid in patients and controls. All postgastrectomy patients with diarrhea failed to absor a portion of a 100-g dose of glucose (quantitated by pulmonary H_2 measurements), but all patients without diarrhea and 10 healthy control subjects absorbed the entire dose. Constant perfusion studies of the terminal ileum in two patients indicat that glucose absorption was least efficient from the most rapidly moving front of the ingested bolu of glucose. These studies suggest that the diarrh observed in some postgastrectomy patients is, in part, the result of malabsorption of carbohydrate due to excessively rapid small bowel transit that is secondary to rapid gastric emptying.

4744 POSITIVE SKIN REACTIONS TO GLUTEN IN COE IAC DISEASE. (Eng.) Baker, P. G.; Read A. E. (Univ. Bristol, Bristol, England). *Q. J. Me* 45(180):603-610; 1976.

Following intradermal challenge with a peptic-tryp digest of gluten dissolved in sterile water (1 g% centration), visible Arthus-type skin reactions we observed in 33% of 55 adults with celiac disease. The patients were either untreated or treated by a gluten-free diet. The amount of gluten intake amo these patients ranged from none to more than 2 g daily. Of 23 patients with untreated disease, pos tive skin reactions occurred in 52%. The skin rea tions to gluten took the form of induration and e thema appearing 2-3 hr after intradermal challenge, becoming maximal at 5-8 hr, and fading over the ensuing 12-18 hr. When skin biopsies obtained from 2 normal controls and from 16 celiac patients displaying positive or negative skin re-

ponses to gluten were compared 5-8 hr after
ntigen challenge, marked polymorph infiltration
atients with negative skin reactions nor in the two
ontrol subjects. When skin biopsies from 14 celiac
atients and from 2 control subjects were treated
ith fluorescein-conjugated anti-human Ig and anti-C_3
omplement to see whether skin challenge sites con-
ained Ig or complement deposits, 8 of the celiac
atients were positive for both anti-Ig and anti-C_3
omplement; the remaining 6 celiac patients and the
control subjects were negative for both tests. All
f the celiac patients positive for these two tests
ad previously shown positive skin reactions and
arked polymorph infiltrate in skin biopsies. Since
o false positive skin reactions were observed among
2 normal controls, skin testing with gluten may
rovide a useful adjunct to the diagnosis and man-
gement of celiac disease, especially on an outpatient
asis.

745 THE PLAIN ABDOMINAL RADIOGRAPH IN PNEUMATOSIS COLI.

(Eng.) O'Connell, D. J.;
ewbury, K. C.; Green, B.; Wyatt, A. P. (Univ. Coll.
osp., London, England). *Clin. Radiol.* 27(4):563-
8; 1976.

inical features and plain film findings in 14
tients with pneumatosis cystoides intestinalis
ere studied over a 3-month to 2-yr follow-up period
determine whether plain film x-ray provides a
liable method for following the clinical course
the disease in response to 5-8 days of treatment
th high concentrations of oxygen. Plain films
ere evaluated by comparison with barium enema
diographs taken before and after treatment. The
aracteristic plain film appearance is a collection
rounded transradiancies projected from the bowel
ll or into the bowel lumen. Cysts smaller than
5 cm were sometimes difficult to distinguish
om gas within the feces, and it is possible to
stake large cysts for normal colonic haustra;
wever, cysts between 0.5 and 4.0 cm in diameter
ere readily identified because the cyst wall
sts a thin dense rim that can be seen against
e background of normal colonic gas and feces.
e thickness of the cyst wall was between 0.5
d 2.0 mm in all cases. Six of 14 patients had
idence of chronic airway obstruction; a pos-
ble cause of pneumatosis coli. The most fre-
ent symptoms presented by the patients were
ndy diarrhea and mucus discharge; symptoms
ere frequently long-standing and intermittent.
tients with diarrhea and nonspecific abdominal
mptoms should have a plain abdominal radiograph
ven though pneumatosis coli is an unusual
planation for these findings) because the plain
lms can be diagnostic. These studies indicate
at the plain abdominal radiograph is also a
mple and reliable method of following the response
patients to treatment.

746 NUCLEAR IMAGING, TOMOGRAPHIC NUCLEAR IMAGING, AND GRAY SCALE ULTRASOUND IN THE
ALUATION OF THE PORTA HEPATIS.

(Eng.) Sample,
F.; Gray, R. K.; Poe, N. D.; Graham, L. S.;
Bennett, L. R. (Center Health Sciences, Los Angeles, CA 90024). *Radiology* 122(3):773-779; 1977.

Twenty-six patients with an equivocal portal defect on conventional nuclear images were evaluated with a multiplane tomographic nuclear scanner and gray scale ultrasound. Of the 17 proved normal cases, 15 were correctly interpreted as normal from the multiplane tomographic nuclear scans, and all 17 were interpreted as normal from the gray scale sonograms. The nine cases that proved to have abnormalities in the portal region were correctly interpreted as abnormal on the multiplane tomographic nuclear scans. The gray scale sonograms were interpreted as abnormal in all nine of the proved abnormal patients. A more specific characterization of the abnormality was usually provided by this technique. Four abnormalities were related to intrahepatic or portal node metastases; one abnormality was related to the extrinsic pressure from a carcinoma of the pancreas; and four were related to a dilated biliary system secondary either to choledocholithiasis, retroperitoneal nodal metastases, or primary carcinoma of the pancreas. The results suggest that these two techniques may be used in a diagnostic sequence for evaluating porta hepatis defects.

4747 COMPARATIVE DIAGNOSTIC VALUE OF GAMMA SCAN, ECHOTOMOGRAPHY AND SPLENOPORTOGRAPHY AND ARTERIOGRAPHY IN HYDATIDOSIS OF THE LIVER. ANALYSIS OF 170 SURGICALLY CONFIRMED CASES.

(Spa.) Cano, J. M.; Perez-Jimenez, F.; de Dios, J. F.; Perez-Carnero, A.; Muro, J. (Departamento de Medicina Interna, Ciudad Sanitaria de la Seguridad Social, "La Paz," Madrid, Spain). *Rev. Clin. Esp.* 140(1):29-42; 1976.

The relative effectiveness of diagnostic techniques in cases of suspected hepatic hydatidosis was examined in a review of 170 cases in which surgical confirmation was available. Laparoscopy was of little value because only one section of the liver surface was accessible. Splenoportography was considered inadequate because the information is also available from arteriography at less risk to the patient. Although a negative tomoechographic study did not exclude the possibility of hydatidosis, a positive result was a reliable indicator of the disease. Given the relative simplicity of this method, it was recommended particularly for use prior to more invasive techniques. Gammagraphy supplied a higher percentage of correct diagnoses of hepatic masses than other methods, especially in masses of the left hepatic lobe. However, this method gave no indication of the nature of the mass (benign or malignant). Arteriography was not as effective as gammagraphy in locating lesions of the left lobe, yet it remained the most effective and complete overall exploratory technique in hydatidosis diagnosis.

4748 A COMPARATIVE STUDY OF OPERATIVE MANOMETRY AND CHOLANGIOGRAPHY.

(Spa.) Suarez Savio, O.; Kin, L. C.; Rodriguez, L. V.; Gonzalez, B. N.;

Rael, A. A.; Mena, R. V. (Instituto de Nefrologia, Hospital docente clinicoquirurgico "Joaquin Albarran," Ave. 26 y R. Boyeros, Cerro, La Habana, Cuba). *Rev. Cubana Cir.* 14(4):363-366; 1975.

Radiomanometry is a simple technique that permits simultaneous monitoring of radiology and manometry of the biliary tract during surgery. This technique was used in 130 patients (122 women, 8 men; average, 45.1 yr) who had biliary tract operations. Preoperative diagnosis was confirmed in 112/130 patients; 17/130 were diagnosed during surgery, 11/17 by radiomanometry, and 6/17 by cholangiography. Because manual injection of the contrast medium, as in cholangiography, produces a high intraductal pressure, obstacles produced by sphincter lesions or small calculi were sometimes undetectable. Radiomanometry, which involves a lower intraductal pressure, was superior to cholangiography for detecting biliary tract lesions.

4749 DIFFERENTIAL DIAGNOSIS OF LIVER DISEASE BY SONOGRAPHY: CORRELATION WITH SCINTIGRAPHY AND ANGIOGRAPHY. (Ger.) Mayrhofer, H. P.; Czembirek, H.; Imhof, H.; Nowotny, Ch.; Pokieser, H. (I. Medizinische Universitatsklinik Wien/Roentgen, Lazarettgasse 14, A-1097 Vienna, Austria). *Wien. Klin. Wochenschr.* 89(13):442-447; 1977.

The diagnostic value of sonography was studied in 44 patients with diffuse hepatic processes and in 58 patients with circumscribed processes. The diffuse processes included liver cirrhosis in 37 cases and lymphogranuloma, fibrosis, hepatomegaly due to polycythemia, immunopathy, and osteomyelosclerosis in 7. The ultrasonic findings were positive in 36 cases, negative in 1, and doubtful in 7. For liver cirrhosis, the findings were positive in 29/37 cases, negative in 1, and doubtful in 7. The distribution of the scintigraphic findings in all 44 patients was exactly the same. Angiography was performed in 17 of these patients; the finding was positive in 12 cases, negative in 1, and doubtful in 4. The circumscribed processes included multiple metastases in 37 patients, multiple hepatic cysts in 4, multiple reticulosarcomas in 1, primary liver carcinoma in 14, abscess in 1, and adenoma in 1. The sonographic findings were positive in 46/58 cases, negative in 11, and doubtful in 1. The scintigraphic findings were positive in 45/58 cases and negative in 6. Sonography was the only method that differentiated between solid and cystic processes. Its main field of application lies in the diagnosis of circumscribed processes. Diffuse processes without clearly defined acoustic borders can be differentiated only on the basis of additional clinical data. The combined use of sonography, scintigraphy, and angiography produces a correct diagnosis in nearly 90% of all cases.

4750 ACTIVITY OF 5' NUCLEOTIDASE IN THE SERUM OF CHILDREN WITH HEPATIC PATHOLOGY. (Fre.) Stephant, E.; Cret, L.; Lahet, C.; Bienvenu, J.; Vial, P.; Mathieu, M. (hopital Debrousse, F 69322 Lyon Cedex 1, France). *Pediatrie* 31(8):771-785; 1976.

Serum enzyme activities were determined in 96 heal neonates and infants and compared to that of infan with viral hepatitis (9), cholestatic icterus (9), or other disorders with secondary hepatic involvement. Enzymic activities measured included 5-nucleotidase (5-NU), aspartate aminotransferase (TGO) alanine aminotransferase (TGP), and alkaline phosphatase (PAL). Three age categories were tested: 0-1 months (11), 1 month-2 yr (17), and 2-14 yr (Kinetic UV was used to determine TGO, TGP, and 5- activities, whereas PAL was measured by the modifi method of Morgenstern with the Technicon SMA 12 micromethod. A constant significant elevation in the activities of TGO, TGP, 5-NU, and PAL was observed in patients with viral hepatitis. The correlation between 5-NU and PAL was statistically significant in viral hepatitis, atresia of the biliary extrahepatic ducts, and in cases of alpha- antitrypsin deficiency. No correlation between T and TGP was noted. In hematological disorders (anemia, metastatic sympathoblastoma, lymphosarco and hepatocarcinoma), 5-NU was always normal whil the transaminase activities varied. A disagreeme between 5-NU and PAL was noted 3 times in metaboli diseases (glycogenesis, 5; intolerance to fructos 2) while the elevation of transaminases attested to a hepatic infection without finding an explanation for this. An increase in transaminases occurred in a 9-month-old infant due to hepatotoxic induced by cyclophosphamide and vincristine. Hep totoxicity in three patients receiving rifampicin or asparaginase could not be definitely attribute to these drugs.

4751 LEVELS OF IMMUNOREACTIVE GLYCINE-CONJUG BILE ACIDS IN HEALTH AND HEPATOBILIARY DISEASE. (Eng.) Demers, L. M.; Hepner, G. W. (Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA 17033). *Am. J. Clin. Pathol.* 66(5):831-839; 1976.

A sensitive radioimmunoassay for cholylglycine, chenodeoxycholylglycine, deoxycholylglycine, and sulfolithocholylglycine was established using ant bodies obtained from rabbits injected with albumi conjugates of these bile acids. This technique was used in the analysis of sera from 25 controls and 100 patients with hepatic disease (alcoholic cirrhosis, hepatitis, cholestasis, and hepatic malignancy). Cholylglycine levels were significantly elevated in most patients and in all hepat biliary disease groups. The increases were simil in all groups, extending to several hundred μmol/ in several patients with malignancy, the elevatio reached <1,000 μmol/1. Chenodeoxycholylglycine w increased predominantly in cholestasis, but not t great an extent as with cholylglycine. This bile was also elevated slightly in the sera of about half the patients with hepatitis and hepatic mali nancy, but in only 5/32 patients with cirrhosis. Deoxycholylglycine was increased mostly in cirrhosis, and only about half the patients in the remaining groups had elevated levels. Sulfoithocholylglycine was elevated in all patients ith hepatobiliary disease. The serum levels of henodeoxycholylglycine, cholylglycine, and sulfoithocholylglycine were measured in one volunteer or 24 hr after the ingestion of 1 g of chenodeoxyholic acid. The cholylglycine level did not hange significantly during the first 3 hr after ngestion, but then rose in response to the ingestion f a meal; this level was within normal limits 5 hr fter the meal. Chenodeoxycholylglycine increased ontinuously 1.5 hr after chenodeoxycholic acid ngestion, reaching a level six times higher than he fasting level until 8 hr after bile acid ngestion; 24 hr later, the level was still signiicantly higher than the fasting level. Sulfoithocholylglycine remained unchanged for the first hr and then increased to twice the fasting level t 24 hr. The results suggest that serum bile cids, particularly sulfolithocholylglycine, are highly sensitive index for hepatic dysfunction.

752 THE USE OF CERULEIN, A NEW GALLBLADDER STIMULATING AGENT, IN THE RADIOLOGICAL XAMINATION OF THE BILE DUCTS. (Spa.) Mosca, L. .; Brasseur, O.; Mosca, L. E. (Laprida 138, Parana, . Rios, Rca, Argentina). *Prensa Med. Argent.* 62(4): 3-87; 1975.

erulein, a decapeptide isolated from frog skin *Hyla cerulea),* is a powerful stimulant of gallladder contraction and evacuation, intestinal eristalsis, pancreatic secretion, and gastric seretion. It has proven superior to the Boyden meal n stimulating biliary motility for cholecystography. erulein acts directly on the gallbladder, whereas he Boyden meal acts by hormonal mediation through he digestive system. Cerulein induces a more inense contraction than the Boyden meal. Administered arenterally, the exact dose of the stimulant is nown and relates predictably to contraction intenity. The period between administration and conraction is short (10 min with 40 mg cerulein), nd 100% of the biliary ducts contract, at some oint during the the test, indicating that none of hese ducts is "atonic" as previously supposed. he authors are confident that cerulein will replace he Boyden meal in the cholecystographic study of allbladder evacuation.

753 THE ROLE OF RADIONUCLIDE IMAGING IN DISEASE OF THE ALIMENTARY TRACT. (Eng.) reeman, L. M.; Rosenthall, L. (Montefiore Hosp. nd Medical Center, 111 East 210th St., Bronx, NY 0467). *Gastrointest. Radiol.* 1(2):187-196; 1976.

GASTROINTESTINAL DISEASES

ESOPHAGUS

4788 THE SIGNIFICANCE OF AN AIR OESOPHAGOGRAM VISUALIZED ON CONVENTIONAL CHEST RADIOGRAPHS. (Eng.) House, A. J. S.; Griffiths, G. J. (Univ. Rochester, Medical Center, Rochester, NY 14642). *Clin. Radiol.* 28(3):301-305; 1977.

The chest radiograph of 29 patients with achalasia and of 24 patients with scleroderma with esophageal involvement were examined for outlining of the entire esophagus (air esophagogram). Three patients (12.5%) with scleroderma showed an air esophagogram. In two cases, there were well-defined, mainly lower zone, pulmonary fibrotic changes, and the air column was seen only on the lateral film. The air esophagogram in the third patient was accentuated with the development of cardiac failure and bilateral pleural effusions. The esophageal caliber was either normal or mildly dilated, and air was present in the gastric fundus. The disease was advanced before the esophageal air was demonstrated. Three patients (10%) with achalasia had an air esophagogram, which was a temporary phenomenon seen only on one examination. The air column was visualized on a well-penetrated postero-anterior film in one patient; it was not shown on the postero-anterior film of another patient but was seen on a right anterior oblique film obtained at the same time. The third patient was in cardiac failure, and the esophageal air was seen only on the lateral film. All three patients gave a few months history of mild dysphagia, the esophagus was mildly dilated without an air fluid level, and there was air in the fundus. Seventy-nine percent of the 29 patients with achalasia and 8% of the 24 patients with scleroderma had constant absence of air in the fundus. The air-filled esophagus has not been previously reported in achalasia; since it is an early manifestation of the disease, it is clinically important.

4789 LOWER ESOPHAGEAL SPHINCTER PRESSURES AND SERUM GASTRIN LEVELS AFTER CHOLINERGIC STIMULATION. (Eng.) Higgs, R. H.; Humphries, T. J.; Castell, D. O.; McGuigan, J. E. (Naval Regional Medical Center, Philadelphia, PA 19145). *Am. J. Physiol.* 231(4):1250-1253; 1976.

The effect of serum gastrin on the response of the lower esophageal sphincter (LES) to bethanechol, a cholinergic agent, was determined by measuring serum gastrin levels and LES pressure in normal controls, in patients with vagotomy and antrectomy (V&A), and in patients with vagotomy and pyloroplasty (V&P). Mean basal LES pressures in the patients and controls were not significantly different. However, compared to controls, the mean basal serum gastrin level in V&P patients was significantly higher ($p< 0.05$), while the level in V&A patients was significantly lower ($p<0.05$). Bethanechol was administered to all subjects, s.c., after an overnight fast, in doses of 0.01, 0.02, 0.04, and 0.08 mg/kg. In controls, 0.08 mg/kg bethanechol produced a significant increase in LES pressure ($p<0.05$), but no change in serum gastrin level. The three higher doses increased LES pressure to a greater extent in V&P patients than in V&A patients ($p<0.05$). Serum gastrin levels did not change in either group; however, background serum gastrin concentrations were significantly greater for V&P patients than V&A patients throughout the study. I.v. infusion of human gastrin I heptadecapeptide (0.06 µg/kg/hr) in controls resulted in a significant increase in LES response to bethanechol ($p<0.01$). The results indicate that higher background serum gastrin level increase the effect of bethanechol upon LES pressure, but they do not markedly influence basal LES pressure.

4790 MOTOR FUNCTION OF THE ESOPHAGUS AFTER REPAIR OF ESOPHAGEAL ATRESIA AND TRACHEO-ESOPHAGEAL FISTULA. (Eng.) Duranceau, A.; Fisher, S. R.; Flye, M. W.; Jones, R. S.; Postlethwait, R. W.; Sealy, W. C. (Hopital Hotel-Dieu de Montreal 3840, Rue St-Urbain Montreal, Quebec H2W 1T8, Canada). *Surgery* 82(1):116-123; 1977.

The nature and etiology of esophageal motor abnorm ties were studied in 11 patients with previous eso geal atresia repair (TEF) and in 10 normal subject (controls). The upper esophageal sphincters (UES) the two groups did not differ in resting pressure, contraction pressure, or coordination. UES relaxation was 100% in the controls and 83% ± 8% in the patients ($p<0.05$). In the proximal esophagus, 100% of the TEF group showed a normal peristaltic wave, coupled with an abnormal nonperistaltic wave. The controls did not show this type of contraction. In the middle esophagus, the mean peak pressure was 30.5 ± 2.0 mm Hg in controls and 14.6 ± 1.0 in the TEF group ($p<0.001$). Coordination was observed in 97 ± 1% of the controls, but in only 27 ± 4% of the patients ($p<0.001$). In the distal 10 cm of esophagus, peak contraction pressures were 43.3 ± 1.6 mm Hg in controls and 21.3 ± 1.1 in the TEF group ($p<0.001$). Coordination was 94 ± 1% in normal subjects and 66 ± 4% in the patients ($p<0.001$). The resting pressure in the patients was significantly higher at all three esophageal levels (proximal, mid, distal) than in controls. In both groups, lower esophageal sphincter function did not show any significant difference except for closing pressure, which was significantly higher in controls (39.9 ± 6.8 mm Hg) than in the TEF groups (21.3 ± 3.0 mm Hg, $p<0.02$). These studies suggest that marked motility abnormalities occur in the repaired esophagus after atresia. These abnormalities are distinctly different from other motor disorders of the esophagus.

4791 TREATMENT OF CORROSIVE BURNS OF THE ESOPHAGUS. (Eng.) Campbell, G. S.; Burnett, H. F.; Ransom, J. M.; Williams, G. D.

4301 W. Markham St., Little Rock, AR 72201). *Arch.*
urg. 112(4):495-500; 1977.

he treatment of 40 patients with caustic ingestion
een over a 20-yr period is reviewed. The median
ge of the patients was 3 yr, and 80% of the
atients were less than 10 yr of age. Strong alkali
as the corrosive in 95% of the cases. The initial
anagement in 18 patients consisted of observation
nly; stricture subsequently developed in 15 of these.
our patients were initially treated with cortico-
teroids alone; all remained free of stricture. One
f 2 patients initially treated with antibiotics
lone developed stricture, and 2 of 14 patients
nitially treated with corticosteroids and anti-
iotics developed stricture. Esophageal bougienage
estored an adequate lumen in 2 patients with short,
oft annular strictures, and right colon interposi-
ion was used for esophageal substitution in 10
atients who had long, dense strictures. This
rocedure produced good results in eight patients
nd fair results in one; in the remaining patient
ith poor results, sloughed colon interposition
ccurred. Early diagnostic esophagoscopy, to the
ppermost level of burn injury only, is recommended
o determine the presence and severity of the
sophageal injury. If esophagoscopy reveals
sophageal burn injury, corticosteroid and anti-
iotic therapy should be continued. If no burn
njury is visualized, the patient is spared unneces-
ary treatment. Long, dense strictures unresponsive
o bougienage place the patient at risk from
nstrumental perforation, and these patients should
ndergo colon interposition through a substernal
xtrapleural tunnel.

792 DIAGNOSTIC DIFFICULTIES IN CARCINOMA OF OESOPHAGUS.

(Eng.) Dasgupta, G.; Das,
P. B. (Miraj Medical Center, Maharashtra,
ndia). *Indian J. Cancer* 13(4):310-313; 1976.

he cases of six patients in whom biopsy failed to
emonstrate surgically proven carcinoma are pre-
ented. These patients were among 219 patients
ndergoing diagnostic esophagoscopy, 39 of whom had
o surgically-proven or biopsy-proven malignancy.
he six patients in whom a false-negative diag-
osis was made had esophageal lesions detected by
oth radiology and esophagoscopy. One reason for
he false-negative biopsy was that an endophytic
rowth from the outer part of the luminal epithelium
ave rise to a lesion discernable by endoscopy but
ith an intact mucosal surface. An esophageal con-
triction resulting from subepithelial spread of the
arcinoma beneath an intact mucosa may give a false
mpression of a tumor; the biopsy taken from this
dematous area will give negative results. A
hird explanation for the false-negative results in
hese patients was that the lesion occurred at the
ardio-esophageal junction; this would result in a
egative biopsy from a blind area of the stomach.

793 APERISTALSIS AND ESOPHAGITIS.

(Eng.)
Simeone, J. F.; Burrell, M.; Toffler, R.;
mith, W. (Yale-New Haven Hosp., New Haven, CT).
adiology 123(1):9-14; 1977.

Aperistalsis of the esophagus was reported in six patients with esophagitis in order to stress its diagnostic value in severe esophagitis. Aperistalsis was observed in reflux (2 patients), caustic (3 patients), and infectious (monileal, 1 patient) esophagitis and was reported to occur both as a transient phenomenon with no further sequelae, and as the initial manifestation of involvement in patients who subsequently suffered stricture. On the basis of biopsy and autopsy specimens (2 patients, showing extensive perineural involvement by inflammatory cells in Auerbach's plexus), a possible mechanism of aperistalsis related to the damage to neurons in auerbach's plexus is suggested. It was concluded that absence of peristalsis is the first significant clue in evaluation of esophageal inflammation in several cases.

4794 EFFECT OF BETHANECHOL ON GASTROESOPHAGEAL REFLUX.

(Eng.) Miller, W. N.; Ganeshappa, K. P.; Dodds, W. J.; Hogan, W. J.; Barreras, R. F.; Arnodorfer, R. C. (Medical Coll. Wisconsin, Milwaukee, WI). *Am. J. Dig. Dis.* 22(3):230-234; 1977.

The acute effects of bethanechol (5 mg, s.c.) on gastroesophageal reflux (GER) and lower esophageal sphincter pressure (LESP) were determined in 27 patients with symptomatic esophagitis. The effect of bethanechol on esophageal acid clearance was also determined in seven patients. Intraluminal pH monitoring prior to bethanechol administration demonstrated free or stress-induced reflux episodes in 18 patients. Patients without reflux had a mean prebethanechol LESP of 18.3 ± 9 mm Hg; this was significantly greater ($p<0.05$) than the LESP in patients with stress reflux (13.6 ± 9 mm Hg) and patients with free, as well as stress, reflux (9.2 ± 4 mm Hg). Bethanechol produced significant LESP elevation ($p<0.001$) in all three patient groups. GER disappeared in seven of the nine patients with stress reflux after bethanechol administration and in six of the nine patients with free and stress reflux. After bethanechol administration, acid clearance times decreased to normal levels in all patients, the mean values before and after administration, being 7.4 ± 2 and 2.7 ± 1 min ($p<0.005$), resp. The fact that some patients with reflux continued to have reflux despite LESP elevation to 30 mm Hg or more suggests that LESP is not the sole factor governing LES competency. Other factors such as improved esophageal emptying may also contribute to the beneficial therapeutic effect of bethanechol in patients with heartburn.

4795 DETECTION OF GASTROESOPHAGEAL REFLUX IN THE PEDIATRIC-AGE PATIENT BY ESOPHAGEAL INTRALUMINAL pH PROBE MEASUREMENT (TUTTLE TEST).

(Eng.) Euler, A. R.; Ament, M. E. (Center Health Sciences, Univ. California, Los Angeles, CA 90024). *Pediatrics* 60(1):65-68; 1977.

The esophageal intraluminal pH probe test (Tuttle test) was used in 24 pediatric patients (aged 4 weeks-16 yr) who had symptoms of gastroesophageal (GE) reflux to determine its sensitivity in detecting gastric acid reflux and to document its prognostic value. Eight children had a positive Tuttle test. Six of these patients failed a trial of medical management and required surgery to control their symptoms. None of these patients had GE reflux on esophagrams. Only 1 of 16 children with a negative test required surgery. This patient also did not have GE reflux on esophagram. The Tuttle test should be included in the diagnosis of pediatric patients with the clinical presentation of GE reflux.

STOMACH

4803 IMMUNOHISTOCHEMICAL AND RADIOIMMUNOLOGICAL DEMONSTRATION OF α_1-FETOPROTEIN IN NONMALIGNANT CHANGES OF HUMAN GASTRIC MUCOSA. (Ger.) Falser, N.; Lederer, B.; Reissigl, H. (Pathologisches Institut der Universitat, Mullerstrasse 44, A-6020 Innsbruck, Austria). *Klin. Wochenschr.* 55(13):635-640; 1977.

The gastric mucosa, gastric juice, and serum from patients with nonmalignant and malignant changes of the gastric mucosa were analyzed for α_1-fetoprotein (AFP) by immunohistochemical (IHCh) and radioimmunological (RI) methods. The IHCh test was positive in 22/25 mucosa samples taken from the periphery of a gastric ulcer and in 13/15 samples from the site of a gastrojejunostomy after Billroth II resection. These patients showed chronic recurrent gastritis. The IHCh test was positive for fo of five patients with gastric adenocarcinoma and cinoma. For the same cases, the RI tests were po tive in 19/25, 12/15, and 4/5, resp. AFP could n detected in serum samples, but it was demonstrate by the RI method in the gastric juice of 16/40 pa tients with gastric ulcer and Billroth II resecti AFP was found in the serum of two of five cancer tients, and in the gastric juice of three of five cancer patients. The results were negative in 86/100 serum samples from healthy donors and in 84/100 samples from patients with gastric disease other than carcinoma or ulcer. The findings show that AFP is not only synthesized by embryonic or neoplastic tissue, but also by regenerating cell systems as an unspecific response to growth stimu tion.

304 ANTRAL GASTRIN CELLS AND SERUM GASTRIN IN ACHLORHYDRIA. (Eng.) Stockbrugger, R.; arsson, L. I.; Lundqvist, G.; Angervall, L. (Sahl- ren's Hosp., Univ. Gothenburg, 413 45 Gothenburg, weden). *Scand. J. Gastroenterol.* 12(2):209-213; 977.

ne number of antral gastrin cells in 45 patients ith achlorhydria due to severe atrophic corpus astritis or gastric atrophy was studied and rela- ed to the serum gastrin level and the degree of hronic antral gastritis. In 24 achlorhydric pa- ients with normal antral mucosa, the serum gastrin evel was 324 ± 56 pM, and the number of gastrin ells was 79.6 ± 7.5 cells/field of vision. The orresponding values for 11 achlorhydric patients ith chronic superficial antral gastritis were not ignificantly different, being 361 ± 186 pM and 3.0 ± 14.4 cells/field of vision, resp.; the cor- esponding values in 10 achlorhydric patients with trophic antral gastritis were significantly dif- erent ($p \leq 0.01$) from those in the other two groups, eing 15.0 ± 3.3 pM and 6.2 ± 3.3 cells/field of ision, resp. In a reference group of 12 subjects 5 with normal antral mucosa and 7 with chronic uperficial antral gastritis), the mean number of ntral gastrin cells was 52 ± 6.5 cells/field of ision. A positive correlation ($p<0.01$) was found etween serum gastrin levels and the mean number f antral gastrin cells/field of vision in the bove patients. These results indicate that, com- ared to subjects in the reference group, the umber of gastrin cells was significantly higher p<0.01) in the achlorhydric patients with normal r superficially inflamed antral mucosa and signif- cantly lower ($p<0.01$) in achlorhydrics with atro- hic antral gastritis. It is concluded that serum astrin generally is a good indicator of the pres- nce or absence of antral atrophic gastritis in chlorhydria.

805 SERUM GASTRIN AND ATROPHIC GASTRITIS IN ACHLORHYDRIC PATIENTS WITH AND WITHOUT ERNICIOUS ANEMIA. (Eng.) Stockbrugger, R.; ngervall, L.; Lundqvist, G. (Sahlgrenska Hosp., 1345 Gothenburg, Sweden). *Scand. Gastroenterol.* 1(7):713-719; 1976.

erum gastrin levels and the presence of circulating ntibodies against parietal cells and cytoplasmic hyroid antigen were compared in 42 patients with ernicious anemia (PA) and 35 achlorhydric patients ithout PA. In addition, the antral and corpus ucosa was examined gastroscopically in 38 patients. ean serum gastrin levels were significantly higher n the PA patients than in those with achlorhydria ithout PA ($p<0.01$). However, the percent distribu- ion of patients with normal or high levels was simi- ar in the two groups. High serum gastrin levels were ssociated with a normal or only slightly inflamed ntral mucosa, but low or normal levels of gastrin ere accompanied by atrophic antral gastritis. ntral atrophy was frequently associated with a eflux of bile-containing duodenal contents to the tomach. Atrophy of the corpus mucosa and degenera- ion or absence of parietal cells were observed in both groups, but the incidence was higher in the PA group. There was no difference in the levels of parietal and thyroidal antibodies between the two groups. The similarities in the symptoms of both groups support the theory that the achlorhydria group may be in a pre-PA state.

4806 LEUKOCYTE MIGRATION STUDIES IN GASTRIC CANCER DETECTION: AN APPROACH TOWARD IMPROVED SPECIFICITY AND SENSITIVITY. (Eng.) Zoller, M.; Matzku, S.; Schulz, U. (German Cancer Res. Center, Im Neuenheimer Feld 280, 6900 Heidelberg 1, W. Germany). *J. Natl. Cancer Inst.* 58(4): 897-904; 1977.

Peripheral blood WBC from patients with gastric cancer and other malignant and nonmalignant diseases and peripheral blood WBC from apparently healthy volunteers were tested in the leukocyte migration inhibition test with the use of four or five different 3-M KCl extracts of gastric cancer tissue. An operational criterion for defining sensitization of patients' WBC was developed, i.e., evidence in an individual sample of WBC of either decreased or increased migration areas (migration index ≤0.79 and ≥1.20, resp.), with three or more antigen extracts. With this definition as an indicator of sensitization, 91% of patients with gastric cancer, compared to 5% and 3% of patients with nonmalignant, nongastric diseases and normal controls, resp., were reactive. Patients with various nongastric cancers were sensitized in 36% of the cases. Gastritis and gastric, as well as duodenal, ulcers did not influence the reactivity of patients' WBC, but considerable sensitization was found in patients with atrophic gastritis or intestinalization. When classified by considering the reaction with individual tumor extracts, the specificity and the sensitivity of the test was markedly diminished; more false negative determinations were found in the group of gastric cancer patients, and the percentage of false positives in the group of nonmalignant diseases increased. The results suggest the presence of tumor-associated antigens in gastric cancer patients, against which the host elicits a cellular immune response. The high incidence of positive reactivity of WBC from patients with gastric cancer, together with the considerable cross-reactivity of WBC from patients with nongastric cancer, points to the expression of antigens with organ-related and widespread specificities

4807 ENDOSCOPIC ASPECT OF EARLY GASTRIC CARCINOMA. (Ger.) Kratochvil, P.; Brandstatter, G. (II. Medizinische Abteilung, Landeskrankenhaus, Auenbruggerplatz 1, A-8036 Graz, Austria). *Acta Med. Austriaca* 4(1):6-11; 1977.

One hundred thirty-one cases of gastric cancer, 25% of which were early gastric cancer, were diagnosed in a series of 3,060 gastroscopies. The symptoms in the early gastric cancer patients included pressure in the epigastric region, malaise, nausea, emesis, loss of appetite, weight loss, hematemesis, and aversion to meat. The duration of the complaints ranged from a few weeks to 2 yr (average, 8.9 months). Twenty-one of these patients were x-rayed prior to endoscopy; results were negative in 10/21, but they prompted gastroscopy in the other 11. Adenocarcinoma was diagnosed histologically in 20 cases, signet-ring cell carcinoma in 4, and solid carcinoma in 1. One patient with signet-ring cell carcinoma had infiltrated regional lymph nodes. Multicentric growth was found in four patients. The size of the tumor ranged from 5 x 5 mm to 37 x 20 mm. Early gastric cancer was found in the gastric stump in four patients 6, 19, 24, and 37 yr after Billroth II surgery for peptic gastric ulcer. Two-thirds of the other 21 cancers were localized to the antrum and one-third to the corpus. The findings indicate the diagnostic value of gastroscopy with biopsy and that the incidence of early gastric cancer is higher than generally believed.

4808 CARCINOMA AND POSSIBLE PRECANCEROUS CHANGES OF THE GASTRIC STUMP AFTER BILLROTH II RESECTION. (Eng.) Domellof, L.; Eriksson, S.; Janunger, K. G. (Univ. Hosp., S-901 85 Umea, Sweden). *Gastroenterology* 73(3):462-468; 1977.

To diagnose early stump carcinoma after Billroth II resection, an endoscopic follow-up was performed in 214 of 459 patients who had undergone primary surgery 20 yr previously for benign ulcer disease. The localization of macro- and microscopic mucosal changes was also studied. Three patients with stump carcinoma were found among 140 patients dead at the follow-up. Six carcinomas, among which two were early carcinomas, were diagnosed in the follow-up group. All carcinomas were found in men. Moreover, 1 patient with multifocal precancerous alterations of the stoma, 2 with tubular adenoma, and 20 with regenerative polyps (9.3%) were found. No significant difference was found in the ratio of original duodenal-gastric ulcer in patients with carcinoma or polyps when compared to other patients. The macro- and microscopic changes were most severe in the stoma, which seems to be a preferential site for carcinoma. The histological changes, however, did not differ in patients with or without carcinoma and polyps. At present, no evidence has been found indicating that histological findings such as chronic atrophic gastritis, intestinal metaplasia, or cystic dilatation of the gastric glands, can be regarded as an early indicator of malignant transformation. To achieve early detection of stump carcinoma, repeated gastroscopic examinations are recommended from 10 to 15 yr after Billroth II resections.

4809 FUNCTIONAL RENAL FAILURE AND HAEMORRHAGIC GASTRITIS ASSOCIATED WITH ENDOTOXAEMIA IN CIRRHOSIS. (Eng.) Clemente, C.; Bosch, J.; Rodes, J.; Arroyo, V.; Mas, A.; Maragall, S. (Hospital Clinico y Provincial, C/Casanova 143, Barcelona, Spain). *Gut* 18(7):556-560; 1977.

The Limulus lysate test was used to determine the presence of endotoxemia in cirrhotic patients to study the association between functional renal failure and endotoxemia. Forty-three patients wit cirrhosis and ascites, 21 with normal renal functi 10 with a progressive functional renal failure (FR and 12 with a steady FRF were studied. Endotoxemi was found in 9 patients with FRF and in none of th 21 with normal renal function ($p<0.01$). A positiv Limulus test was almost exclusively associated wit a progressive FRF (8/10 patients), and all but one of these patients died. Renal function improved as endotoxemia disappeared in the survivor. Endotoxemia was also associated with hemorrhage due to acute erosions of the gastric mucosa, being presen in six of the seven patients with this complicatio Intravascular coagulation was not found in any patient. The Limulus test was positive in the ascit fluid in 18 of 21 patients tested, although only 2 of them had peritonitis. These results suggest that endotoxemia may play a critical role in the development of progressive renal failure and hemorrhagic gastritis in cirrhosis, and emphasize the potential risk of procedures involving reinfusion of ascitic fluid.

4810 EFFECT OF CHOLESTYRAMINE ON THE SYMPTOMS OF REFLUX GASTRITIS: A RANDOMIZED, DOUB BLIND, CROSSOVER STUDY. (Eng.) Meshkinpour, H.; Elashoff, J.; Stewart, H., III; Sturdevant, R. A. (Irvine Medical Center, 101 City Drive South, Orange, CA 92668). *Gastroenterology* 73(3):441-443 1977.

To examine the value of cholestyramine in the treatment of the symptoms of postsurgical reflux gastritis, a randomized, double-blind crossover st was carried out in 16 patients. No differences in frequency of abdominal pain, nausea, vomiting, or bitter taste were observed among cholestyramine (4 g, t.i.d., for 3 weeks), placebo, and routine (dietary restriction and *ad libitum* antacid) treatment periods. It is concluded that this regimen o cholestyramine is ineffective in symptomatic treatment of bile reflux gastritis.

4811 DUODENOGASTRIC REFLUX AND ANASTOMOSIS UL CERS. AN EXPERIMENTAL STUDY. (Ger.) Dahm, K.; Eichfuss, H. P.; Knipper, A.; Mitschke, (Abteilung Allgemeinchirurgie der Chirurgischen Klinik, Martinistrasse 52, D-2000 Hamburg 20, W. Germany). *Z. Gastroenterol.* 15(1):9-20; 1977.

The effect of duodenal bypass with or without duodenogastric reflux on the development of ulcers of an anastomosis between the stomach and the duodenu was studied in male Wistar rats. Gastroduodenal reflux was produced in 32 rats by bypassing the py lorus. Duodenal stasis was observed in 24. Stasi and the continuous reflux of bile and pancreatic secretion were the major etiological factors of th peptic ulcers found in 29/32 rats. Duodenogastric reflux without a pyloric bypass was produced in 10 animals. They showed only slight duodenal stasis, and the incidence of ulcers was considerably lower (2/10). Duodenal bypass without duodenogastric reflux was produced in 12 rats. They showed no du denal stasis at all, and only one rat developed an ulcer. Duodenogastric reflux significantly inhibited hydrochloric acid secretion; in view of the results, however, hydrochloric acid plays no important role in the genesis of experimental anastomotic ulcers. The findings suggest that reflux and stasis are the etiological factors of jejunal peptic ulcer in man.

4812 MULTIPLE RECURRING GASTRIC EROSIONS (APHTHOUS ULCERS). (Eng.) Morgan, A. G.; McAdam, W. A. F.; Pyrah, R. D.; Tinsley, E. G. F. (Airedale General Hosp., Steeton, Keighley, West Yorkshire, England). *Gut* 17(8):633-639; 1976.

Five patients (ages 29-56 yr) who had repeated endoscopy because of continuing dyspeptic symptoms associated with a negative barium meal examination are described. All presented with upper abdominal pain (which included hematemesis in one patient) and with longstanding barium-negative symptoms. On endoscopy, they were found to have aphthous ulcers of the stomach; on prolonged endoscopic followup, these were shown to be persistent. No etiological cause could be found, and conventional management (antacids, metoclopramide, carbenoxolone) failed to control either the symptoms or ulceration. In two patients, a highly selective vagotomy was carried out after a year of unsuccessful medical therapy. In both patients, the relief of symptoms was dramatic, and repeated endoscopies have shown no further aphthous ulceration. The ulceration had been accompanied by chronic gastritis in one of these patients. The favorable response to vagotomy in these patients suggests that future patients could be treated with H_2 receptor antagonists, which reduce basal and maximal acid output and pepsin to the same extent as does vagotomy.

4813 THE GLANDULAR CYST, A POLYPOID LESION OF THE GASTRIC MUCOSA. (Ger.) Elster, K.; Eidt, H.; Ottenjann, R.; Rosch, W.; Seifert, E. (Pathologisches Institut, Stadtische Krankenanstalten, Kulmbacher Strasse 23, 8580 Bayreuth, W. Germany). *Dtsch. Med. Wochenschr.* 102(6):183-187; 1977.

Epithelial gastric polyps were reclassified on the basis of a histological study of >500 cases. They were found to consist of: (1) focal hyperplasia and hyperplasiogenic polyps arising from the gastric pit and leading to hyperplasia or hyperplasia with adenomatous components; (2) highly differentiated adenomas arising from glandular bodies, leading to blastomas of the antrum, pylorus, and cardia; (3) moderately differentiated adenomas from glandular ducts, leading to blastomas, chiefly of the cardia; (4) protruding borderline lesions from glandular ducts, leading to atypical hyperplasia and blastomas; and (5) early carcinomas from glandular ducts, leading to blastomas. One hundred ten cases of polypoid mucosal changes could not be classified. The polyp-like structures grow to a maximum diameter of 8 mm and are characterized histologically as noninflammatory cysts of different sizes located within the fundal glands. They may be the result of hamartomas or functional secretory disorders. These glandular cysts, which do not fit the picture of cystic gastritis, have not been described previously. They are of clinical significance since they must be differentiated from gastric polyposis.

4814 ULTRASONIC PATTERNS OF SPACE OCCUPYING LESIONS OF THE STOMACH AND THE INTESTINE. (Eng.) Lutz, H. T.; Petzoldt, R. (Dept. Internal Medicine, Univ. Erlangen-Nurnberg, D852 Erlangen, W. Germany). *Ultrasound Med. Biol.* 2(2):129-132; 1976.

Experience with 40 patients in whom ultrasonic scanning was used in the detection of space-occupying lesions of the stomach and intestine is presented. Ultrasonic scanning revealed a lesion below the edge of the left liver lobe or on the left side of the liver (corresponding to a gastric lesion) in 24 patients. In 15 of these patients, a gastric tumor had already been diagnosed by x-ray examination, and ultrasound was carried out to examine the liver. In the remaining patients, ultrasound was the primary examination. A small intestinal lesion was detected by ultrasound in five patients, three of whom had a palpable tumor. A tumor of the large intestine was visible using ultrasonography in 11 patients; in 4 cases, the tumor was primarily detected by ultrasonic scanning. The typical sonographic pattern of the lesions consisted of strong echoes in the center and a virtually anechoic mantle. Malignant tumors were diagnosed at endoscopy or operation in 21 patients with a stomach lesion and in 3 patients with a small intestinal lesion. The nonmalignant lesions included one case showing giant gastric folds typical of Menetrier's disease, two large gastric ulcers, an inflammatory small intestinal lesion due to Crohn's disease, and a small intestinal perforation.

4815 ULTRASTRUCTURAL OBSERVATIONS OF THE MYENTERIC PLEXUS OF THE PYLORUS IN INFANTILE HYPERTROPHIC PYLORIC STENOSIS. (Eng.) Challa, V. R.; Jona, J. Z.; Markesbery, W. R. (Univ. Kentucky Medical Center, Lexington, KY 40506). *Am. J. Pathol.* 88(2):309-322; 1977.

The ultrastructure of myenteric plexuses and smooth muscle of the pylorus obtained by biopsy at pyloromyotomy in five infants with hypertrophic pyloric stenosis were studied. Pyloruses from two infant and two adult rabbits and two adult rats were used as controls. The principal findings in the plexuses of the patients were moderate numbers of variably sized, swollen degenerating axons that contained dense bodies, lamellated figures, vacuoles, granular or fibrillar material, and swollen mitochondria. Neurons in the plexuses showed no definite abnormalities. Although these findings do not confirm previous light microscopic observation of neuronal changes in the pyloric myenteric plexuses, they do not exclude a neurogenic mechanism for this disorder. The presence of small immature neurons and large mature neurons suggests that neuronal maturation and development in infantile hypertrophic pyloric stenosis are not impaired as previously reported. No ultrastructural changes were found in interstitial cells of the myenteric plexuses. Except for hypertrophy of the circular smooth muscle layers, no specific alterations were found in muscle fibers of the pylorus.

4816 SURGICAL PROPHYLAXIS OF GASTRODUODENAL COMPLICATIONS ASSOCIATED WITH RENAL ALLOTRANSPLANTATION. (Eng.) Uhlschmid, G.; Largiader, F. (Kantonsspital, CH-8091 Zurich, Switzerland). *World J. Surg.* 1(3):397-405; 1977.

The value of prophylactic ulcer operations (i.e., vagotomy) in potential renal allograft recipients who appeared to be likely to develop a peptic ulcer was studied. From 1971 to 1975, 226 patients received kidney allografts, and prophylactic ulcer surgery was regularly performed prior to kidney transplantation in those who had a history of previous ulcer, symptoms of peptic ulcer, a demonstrable ulcer on x-ray or endoscopy, gastric acid hypersecretion, or a temperment conducive to the development of peptic ulcer. The results of this prophylactic program were compared with those of the previous period from 1964 to 1970 when prophylactic ulcer surgery was not used in 77 kidney allograft recipients, and with those of the concurrent period obtained in 194 recipients who did not receive surgical prophylaxis. Initially, the prophylactic operation was truncal vagotomy with pyloroplasty, then it was proximal selective vagotomy (PSV) without pyloroplasty, and finally it was selective gastric vagotomy with pyloroplasty (SGV + P). The incidence of gastroduodenal complications in patients who did not receive prophylactic ulcer surgery was 22.1% during the period 1964-1970, and 15.9% during the period 1971-1975; the mortality rates from gastroduodenal complications were 10.4% and 4.6%, resp. In contrast, only 1 of 32 renal transplant recipients who underwent prior prophylactic ulcer surgery developed a gastrointestinal complication, and there were no deaths in the prophylactic surgery group. Two patients developed fatal ischemic gastric necrosis following PSV, which led to the adoption of SGV + P as the prophylactic operation of choice. Prophylactic ulcer surgery has substantially reduced the incidence and mortality of gastroduodenal complications following renal transplantation.

STOMACH

Peptic Ulcers

4832 POSTPRANDIAL GASTRIC, PANCREATIC, AND BILIARY RESPONSE TO HISTAMINE H_2-RECEPTOR ANTAGONISTS IN ACTIVE DUODENAL ULCER. (Eng.) Longstreth, G. F.; Vay, L. W.; Go, M. D.; Malagelada, J. R. (Mayo Clinic, Rochester, MN). *Gastroenterology* 72(1):9-13; 1976.

The effect of 200 mg and 300 mg doses of cimetidine (an H_2-receptor antagonist) taken orally with an ordinary meal on gastric, pancreatic, and biliary functions of 10 male patients with active gastric duodenal ulcer was studied. The inhibition of secretory output of postprandial gastric secretion in duodenal ulcer after 200 mg and 300 mg cimetidine administration, resp., was acid, 38.5 ± 3.2%, 65.5 ± 7.8%; pepsin, 30.3 ± 12.0%, 31.6 ± 11.8%; and volume, 27.4 ± 5.9%, 39.5 ± 11.4%. The 300-mg dose markedly reduced gastric secretion without affecting gastric emptying or pancreatic or biliary function; therefore, this dose of cimetidine should prove effective in the management of acid-peptic disease. Because cimetidine appears to be less effective postprandially than during nocturnal fasting, a larger dose or adjuvant therapy may be indicated with meals.

4833 COMPARISON OF AN H_2 RECEPTOR ANTAGONIST AND A NEUTRALIZING ANTACID ON POSTPRANDIAL ACID DELIVERY INTO THE DUODENUM IN PATIENTS WITH DUODENAL ULCER. (Eng.) Deering, T. B.; Malagelada, J. R. (Mayo Clinic, Rochester, MN 55901). *Gastroenterology* 73(1):11-14; 1977.

The effects of cimetidine and antacid on postprandial acid delivery into the duodenum were compared in six duodenal ulcer patients. Cimetidine (400 mg) with an ordinary solid meal decreased the 4-hr delivery of titratable acid and hydrogen ion into the duodenum by 63% and 86%, resp., ($p<0.01$ versus control). Liquid Maalox (30 ml), 1 and 3 hr after an identical meal, reduced 4-hr delivery of acid by 47% and 74%, resp. ($p<0.01$). During the study period, the H_2 receptor antagonist reduced gastric acidity and the delivery of acid into the duodenum continuously. The liquid-neutralizing antacid produced a more fluctuating decrease in these parameters. However, in these dosages, the magnitude and duration of the acid-reducing effect were similar for both treatments.

4834 IS REDUCED RELEASE OF GASTRIN THE MECHANISM OF ULCER HEALING AFTER GASTROENTEROSTOMY? (Eng.) Lam, S. K.; Sircus, W.; Byrnes, D. J. (Univ. Hong Kong, Hong Kong). *Am. J. Dig. Dis.* 22(5):397-401; 1977.

To study how gastroenterostomy promotes healing, the effect of this procedure on the gastrin response to meals was studied 3 weeks and 26 weeks after surgery in nine patients. Nine normal subjects served as controls. The patients (aged 24-58 yr, mean 39.7 yr) all had uncomplicated duodenal ulceration and a mean acid output (MAO) response to pentagastrin of 6 μg/kg before surgery. As compared with the preoperative levels, the gastrin response to the standard meal was lower at 30, 40, and 60 min after 3 months and after 6 months. A significant drop occurred in the postprandial levels at 45 and 60 min after 6 months, and at 90 min after both 3 and 6 months ($p<0.05$ at 45 min, $p<0.01$ at 60 min, $p<0.001$ at 6 months). The mean integrated gastrin response (IGR) to a meal was higher in the unoperated patients than in the controls ($p<0.0005$). The IGR fell to between 35% and 75% of the preoperative levels in five of seven patients. Six months after operation, the IGR in all but one patient was significantly lower than before ($p<0.05$), the mean percentage fall being 31.1%. The mean IGR at 6 months was significantly greater than that of the controls. These studies show that gastroenterostomy is followed by significant changes in the postprandial secretion of gastrin during both the gastric and the intestinal phases of meal response.

4835 GASTRITIS DUODENITIS, AND CIRCULATING LEVELS OF GASTRIN IN DUODENAL ULCER BEFORE AND AFTER VAGOTOMY.

(Eng.) Meikle, D. D.; Taylor, K. B.; Truelove, S. C.; Whitehead, R. (Radcliffe Infirmary, Oxford, England). *Gut* 17(9):719-728; 1976.

Biopsy specimens were taken from five standard sites in the stomach and from the duodenal bulb in 20 patients with duodenal ulcer to investigate the association of gastritis and duodenitis with duodenal ulcer. The effects either of truncal vagotomy and pyloroplasty (TVP) or of highly selective vagotomy with drainage (HSV) on the stomach and duodenal bulb mucosa were also investigated in these patients. All investigations were carried both before and 3 months after surgery. Gastritis was present in almost all patients with duodenal ulcer, but it tended to be concentrated and to be most severe in the antrum and along the lesser curve of the stomach in over half the patients. Gastritis was also present in the body of the stomach, but only three patients had gastritis in the fundus. Chronic duodenitis was found in the duodenal bulb in all these patients. After vagotomy, there was a marked increase in both the extent and severity of the proximal gastritis in both treatment groups, but the distal gastritis remained almost unchanged. There was no significant change in the incidence of duodenitis after vagotomy, but its severity was lessened. No correlation was found between the peak acid output (PAO) in response to betazole hydrochloride and the severity of the gastritis or the duodenitis either before or after operation, with one exception; the postoperative PAO was significantly less in those patients who developed a severe proximal gastritis after vagotomy. No relationship was found between the severity of the distal gastritis and the serum gastrin levels. No correlation was found between either the basal or peak acid output and the corresponding serum gastrin levels before or after either type of vagotomy. This suggests that lesser vagal activity than that occurring during an insulin test is not an important factor in the stimulation of gastrin release from the antrum.

4836 STIMULATION OF GASTRIC INHIBITORY POLYPE TIDE IN NORMAL AND DUODENAL ULCER PATIEN

(Eng.) Cataland, S.; O'Dorisio, T. M.; Brooks, R. Mekhjian, H. S. (410 West 10th Ave., Columbus, OH 43210). *Gastroenterology* 73(1):19-22; 1977.

To investigate the role of gastric inhibitory polypeptide (GIP) in the hypersecretion associated wit duodenal ulcer, serum GIP concentrations in 11 healthy subjects and 16 duodenal ulcer patients we compared after the stimulation of GIP release by a mixed meal. Fasting and postprandial serum gastri and GIP concentrations were measured by radioimmun assay at frequent intervals. The duodenal ulcer patients showed an augmented and significantly greater release of GIP compared to normal subjects at 5, 15, 30, 60, 120, and 180 min after the ingestion of the test meal ($p<0.05$). The fasting gastr level in the controls was 32 ± 2 pg; after the mea rose to 84 ± 10 and 80 ± 6 pg/ml at 5 and 15 min, declining thereafter to 79 ± 6, 74 ± 6, 48 ± 3, an 42 ± 3 pg/ml at 30, 60, 120, and 180 min, resp. T mean fasting gastric concentration in the duodenal ulcer patients was 64 ± 6 pg, and it rose to 147 ± 29, 186 ± 43, and 192 ± 35 pg/ml at 5, 15, and 30 min and declined to 161 ± 35, 115 ± 18, and 106 ± pg/ml at 60, 120, and 180 min, resp. All values were significantly greater than those in controls ($p<0.05$).

4837 PERFORATED DUODENAL ULCER: IS THE DISTINCTION BETWEEN ACUTE AND CHRONIC VALID

(Eng.) Dent, D. M.; Bank, S.; Louw, J. H. (Groote Schuur Hosp., Cape Town, South Africa). *S. Afr. Med. J.* 51(16):529-531; 1977.

Perforations of acute and chronic duodenal ulcers were compared in 70 patients to identify any biolo ical features that may help to differentiate acute and chronic ulcers. Age, racial incidence, acid output, and histology of the ulcer at the time of perforation were analyzed. The mean age for the acute group was 40 yr and for the chronic group 37 yr. The proportions of acute to chronic remained approximately 1:3 in each decade. The mean basal acid output measured 6 weeks postoperatively was 3.9 ± 2.3 mEq/hr for the acute group and 4.5 ± 3.1 mEq/hr for the chronic group. The mean maximal acid output for the acute group was 25.2 ± 7.7 mEq/hr and for the chronic group, 27.4 ± 10.3 mEq/hr ($p>0.2$). Biopsy of the ulcer edge at the time of closure was carried out in 14 acute patients and 3 chronic patients. Fibrosis was present in all acut cases and in 25 chronic cases. Granulation tissue occurred in eight chronic cases. The results show no significant differences between the ulcer types, using the above variables. The authors conclude that the only true "acute" ulcer is the rare stress ulcer.

SMALL INTESTINE

4865 THE CONTINENT ILEAL POUCH: ABSORPTIVE AND MOTOR FEATURES. (Eng.) Gadacz, T. R.; Kelly, K. A.; Phillips, S. F. (Veterans Admin. Hosp., 3900 Loch Raven Blvd., Baltimore, MD 21218). *Gastroenterology* 76(6):1287-1291; 1977.

The absorptive and motor features of ileal pouches were studied in eight patients 6-40 months after proctocolectomy and construction of a continent ileal pouch, to determine whether the mucosa of the pouch retains the properties attributed to normal ileum. Test solutions of 100 or 200 ml, containing a nonabsorbable marker (phenolsulfonphthalein), were placed in the pouch and sampled serially for 1 hr; an oro-intestinal tube was used to prevent contamination of the pouch by endogenous secretions. Sodium was absorbed from test solutions containing 25, 75, and 120 mM sodium; absorption
from the lowest concentration represented movemen
against a concentration gradient of approximately
120 mM. The mucosal potential difference (PD) wa
small in magnitude (1-3 mV) but consistently negative, and sodium was thus absorbed by the pouch
against a steep electrochemical gradient. Chlori
was also absorbed against marked concentration
gradients, but its absorption was favored by the
small negative mucosal potential. Chloride absor
tion was greater in magnitude than corresponding
absorptions of sodium. Water was always absorbed
whenever electrolyte was absorbed. The addition
60 mM glucose increased the negativity of mucosal
PD in all pouches (from 6.2 to 16.0 mV). The pou
absorbed vitamin B_{12} that was instilled together
with intrinsic factor. There was a striking lack
of secondary bile acids in the duodenal bile in a
patients (0-10.8% secondary bile acids); this fac

and the distribution of the primary bile acids suggests that decreased dehydroxylation of bile acids occurs in pouch patients. The pattern of motility in the pouches was consistent with that reported previously for normal ileum. These results indicate that the functions of the mucosa and smooth muscle of the continent ileal pouch are similar to those of the normal ileum.

4866 HOME TOTAL PARENTERAL NUTRITION: AN ALTERNATIVE APPROACH TO THE MANAGEMENT OF CHILDREN WITH SEVERE CHRONIC SMALL BOWEL DISEASE.

(Eng.) Byrne, W. J.; Halpin, T. C.; Asch, M. J.; Fonkalsrud, E. W.; Ament, M. E. (UCLA Center for the Health Sciences, Los Angeles, CA 90024). *J. Pediatr. Surg.* 12(3):359-366; 1977.

The use of a home program of total parenteral nutrition (HTPN) for the management of six children (ages, 2.25-17 yr) with severe chronic small bowel disease over periods ranging from 1-11 months is described. There were two cases of chronic idiopathic intestinal pseudo-obstruction syndrome and one case each of Crohn's disease with enterocutaneous fistula, unclassified sprue with selective immunoglobulin A deficiency, short bowel syndrome with enterocutaneous fistula secondary to an anastomotic leak, and Crohn's disease with short bowel syndrome. Criteria for instituting this therapy were the inability to maintain fluid and nutritional balance on a therapeutic diet or p.o. formula or a need for 30 or more days of conventional total parenteral nutrition (TPN). The HTPN was accomplished using a Broviac catheter. The proximal end of this centrally placed silastic catheter exits on to the skin of the chest wall through a s.c. tunnel and has a Leur lock which allows it to be sealed off with a screw cap when not being used for TPN. The six patients had a total of 1,139 days on HTPN with one episode of catheter sepsis and one localized infection at the catheter site. None of the catheters clotted, but one was accidentally dislodged. Small bowel adaptation, which allowed gradual discontinuance of HTPN and reinstitution of total p.o. alimentation, occurred in four of the six patients. The HTPN program is recommended for children and adolescents with severe chronic small bowel disease who face prolonged hospitalizations.

4867 MORPHOLOGY OF THE SMALL BOWEL IN SMALL BOWEL ATRESIA AND STENOSIS.

(Ger.) Willnow, U. (Klinik und Ambulanz fur Kinderchirurgie des Bereichs Medizin, Karl-Marx-Universitat, Oststrasse 21-25, DDR-705 Leipzig, E. Germany). *Zentralbl. Chir.* 102(12):737-743; 1977.

The morphologic and pathogenetic aspects of small intestinal atresia and stenosis in 24 newborn babies operated on for these conditions are described. Atresia was found in 20 infants; it was localized to the ileum in 15 and the jejunum in 4; multiple atresia was found in 1. Stenosis was found in the jejunum of two infants and in the ileum of two others. Morphologically, the atretic section was characterized by flat, thin mucosa with a reduced number of villi, and the absence of longitudinal and circular stratification of the muscular layer. Inflammatory processes, circulatory disorders, or severe regressive structural changes of the mucosa were seen in all but five cases. Necrosis and ulceration of the mucosa were seen in 15. The mucosa was missing in four cases, the submucosal and myenteric plexus in five. The 10- to 15-cm inflated pre-atretic section usually showed a marked reduction of the thickness of the mucosa, submucosa, and muscular layer. Hemorrhagic and inflammatory processes, sometimes culminating in perforation and necrosis, were seen in 15 cases. The mouth of the intestine showed signs of compensatory hypertrophy. In stenosis, no major structural changes were seen apart from a marked hypertrophy of the muscular wall in the prestenotic section. Fetal accidents (necrosis, calcification, fibrosis, and hemosiderophages) and pathological changes of the intestine are assumed to be etiological factors in most cases of atresia. The prognosis of small intestinal atresia is determined by its localization and by the presence or absence of additional abdominal malformations (omphalocele, gastroschisis, and volvulus) and diseases such as mucoviscidosis and fetal peritonitis.

4868 PATHOPHYSIOLOGY OF ENLARGEMENT OF THE SMALL BOWEL FOLD.

(Eng.) Olmsted, W. W.; Reagin, D. E. (Armed Forces Inst. Pathology, Washington, DC 20306). *Am. J. Roentgenol.* 127(3):423-428; 1976.

The pathophysiology underlying enlargement of the valvulae conniventes during primary small bowel disease is described along with the most typical diseases with prominent folds leading to malabsorption. Lymphoma and regional enteritis are the most frequent small bowel diseases that cause malabsorption associated with thickening of folds; fold enlargement in both diseases is the result of packing of the lamina propria and submucosa with cells and edema. In Whipple's disease, the prominent fold is the major radiologic and pathologic finding, and the disease is distinguished microscopically by the presence of PAS-positive macrophages in the lamina propria of the small bowel wall. In early amyloidosis, glycoprotein is deposited in the lamina propria and submucosal perivascular spaces; as the disease progresses, the entire wall may be infiltrated and converted into a rigid tube. In lymphangiectasia, the striking pathologic abnormality is dilatation of the lymphatics of the lamina propria and submucosa. Nodular thickening of folds is the most prominent feature of nodular lymphoid hyperplasia associated with immunoglobulin deficiencies and infestation by *Giardia lamblia*. Secondary radiologic signs include mild dilatation and hypersecretion. When those diseases or conditions that occur the most frequently have been excluded (cardiac, hepatic or renal edema, regional enteritis, and lymphoma), Whipple's disease, amyloidosis, lymphangiectasia, and nodular lymphoid hyperplasia should be the main considerations in differential diagnosis of malabsorption. The diagnosis can be made radiologically on the basis of secretions and the characteristics and distribution of the enlarged folds. Lymphangiectasia and nodular lymphoid hyperplasic cause increased secretions. In Whipple's disease, the folds are generally irregular and somewhat disordered; in amyloidosis and lymphangiectasia the folds are more regular; those seen in nodular lymphoid hyperplasia are nodular. In Whipple's disease, the enlarged folds are located primarily in the duodenum and jejunum; the same is true for nodular lymphoid hyperplasia, although other parts of the small intestine may be affected. Thickening of the folds in amyloidosis and lymphangiectasia is generally distributed throughout the entire small bowel.

4869 THE IMMUNOGLOBULIN-BEARING CELLS IN THE LAMINA PROPRIA AND THE CLINICAL RESPONSE TO A GLUTEN-FREE DIET IN DERMATITIS HERPETIFORMIS. (Eng.) Vermeer, B. J.; Lindeman, J.; van der Harst-Oostveen, C. J. G. R.; Pena, A. S.; van Vloten, W. A. (Univ. Hosp., Rihnsburgerweg 10, Leiden, Netherlands). *Arch. Dermatol. Res.* 258(3):223-230; 1977.

Multiple duodenal and jejunal biopsies were carried out in 17 patients with dermatitis herpetiformis (DH) to determine the effect of a gluten-free diet on the 4,4'-sulfonyldianiline dose and on the numbers of immunoglobulin-containing cells in jejunal mucosa. In all patients, the small intestinal biopsy specimens showed histopathological changes compatible with celiac disease. Fourteen patients maintained a gluten-free diet (GFD) for more than 8 months. The small intestinal lesions improved in all patients investigated during the GFD. The dosage of 4,4'-sulfonyldianiline needed to control the skin lesions could be reduced by more than 50% in four patients and the drug could be stopped in five patients on GFD. The immunoglobulin-bearing cells in the lamina propria were counted in eight patients not on GFD, in six patients on GFD, and in eight healthy controls. The numbers of IgA-, IgM- and IgG-bearing cells were increased in most of the DH patients who were not on GFD. The number of IgM-bearing cells in the DH patients who were on GFD was the same as that in the control group. This may indicate a mainly IgM response in the lamina propria induced by gluten.

4870 MESODIVERTICULAR BAND. (Eng.) Johnson, G. F.; Verhagen, A. D. (Children's Medical Center, 1735 Chapel St., Dayton, OH 45404). *Radiology* 123(2):409-412; 1977.

Experience with Meckel's diverticula in eight patients is summarized, with particular emphasis on the importance of mesodiverticular band (MDB) in the production of intestinal obstruction as one of the important complications of Meckel's diverticulum. Six of the eight patients demonstrated evidence of intestinal obstruction. In two cases, MDB obstruction was suggested preoperatively, as the plain abdominal radiographs showed fluid-distended small bowel loops in the right lower quadrant. Small bowel obstruction was the only radiological observation in four cases. In one case, MDB was diagnosed preoperatively by barium contrast examination, and in two cases a soft-tissue mass was identified. In the remaining patient, who had presented with acute appendicitis rather than symptoms of intestinal obstruction, small bowel ileus together with medial cecal soft-tissue deformity were seen radiologically. Although gangrenous Meckel's diverticulum complicated one case, there was no free intraperitoneal air to indicate perforation. The anatomic features and the mechanism by which MDB produces obstruction are reviewed. The MDB is an embryologic remnant of the vitelline circulation that carries the arterial supply to Meckel's diverticulum. In the event of an error of involution, a patent or nonpatent arterial band persists and extends from the mesentery to the apex of the antimesenteric diverticulum. This creates a snare-like opening through which bowel loops may herniate and become obstructed, as occurred in the six cases of obstruction in this series.

4871 EOSINOPHILIC GASTROENTERITIS WITH ESOPHA INVOLVEMENT. (Eng.) Dobbins, J. W.; Sheahan, D. G.; Behar, J. (Yale Univ. Sch. Medicin 333 Cedar St., New Haven, CT 06510). *Gastroenterol* 72(6):1312-1316; 1977.

The case of a 51-yr-old man with clinical and hist logical evidence of eosinophilic enteritis with esophageal involvement is presented. The patient a lifelong history of asthma and hay fever and was investigated because of symptoms of esophageal spas Esophageal biopsies revealed elongated papillae an basal zone hyperplasia of the epithelial layer wit eosinophilic infiltration of the lamina propria an muscularis mucosae. There was no evidence of refl Small bowel biopsies revealed a flat mucosal patte with absent or blunted villi, tall columnar surfac epithelium, and eosinophilic infiltration of the lamina propria. He did not respond to a gluten-fr diet. This patient is thought to have eosinophili gastroenteritis with esophageal involvement, the first such case reported.

4872 INTRAMURAL DUODENAL HEMATOMA IN CHILDREN THE ROLE OF THE RADIOLOGIST IN ITS CONSERVATIVE MANAGEMENT. (Eng.) Mahboubi, S.; Kaufmann, H. J. (Children's Hosp., 34th St. and Civic Center Blvd., Philadelphia, PA 19104). *Gast intest. Radiol.* 1(2):167-171; 1976.

The clinical and radiologic findings in six childr with intramural duodenal hematoma are reported, an the case reports of two patients are presented. T hematoma was caused by blunt abdominal trauma in all cases. The symptoms included nausea, vomiting, upper abdominal pain, and lethargy. Serum amylase was elevated in only one case. Barium examination of the upper gastrointestinal tract was performed in all instances after plain abdominal films excluded the possibility of intestinal perforation. Subsequent conservative management consisted of restricted p.o. intake, i.v. infusions of fluids and electrolytes, and nasogastric suction. Spontaneous resolution of the hematoma, as judged by the complete disappearance of symptoms and the free passage of barium through the duodenum, occurred 2-20 weeks after the injury. No complications were encountered.

4873 RADIOGRAPHIC CHANGES AFTER SMALL BOWEL BYPASS FOR MORBID OBESITY. (Eng.) Wade, D. H.; Richards, V.; Burhenne, H. J. (Children's Hosp. San Francisco, P.O. Box 3805, San Francisco, CA 94119). *Radiol. Clin. North Am.* 14(3):493-498; 1976.

Normal roentgenographic findings following small bowel bypass for morbid obesity are reviewed for 38 patients who were studied 1 yr or more after surgery. Anastomosis of the end-to-side jejunoileostomy was visualized in 36 patients. Reflux of contrast material into the bypassed small bowel segment was observed in 29 patients. In 31 patients, the postoperative mucosal pattern showed an increase in the thickness of the valvulae conniventes. Small bowel transit time was decreased to less than 15 min in all 38 patients. Other findings included: increased small bowel diameter in 33 patients, large bowel dilatation in 19 patients, and increased air-fluid levels in the large and small bowel in 31 patients. The presence of multiple intestinal air-fluid levels and the distention of the jejunum and colon are common and expected postoperative sequelae of small bowel bypass procedures for morbid obesity, and the radiologist must be familiar with these findings to avoid the misdiagnosis of bowel obstruction. Marked colon distention and even megacolon also occur normally after small bowel bypass operations. Faint or absent gallbladder visualization after oral medication is a further roentgenographic finding with small bowel bypass procedures. Two-day medication for oral cholecystography followed by i.v. cholangiography is indicated in the event of nonvisualization.

4874 S-TRYPTOPHAN CONCENTRATIONS AFTER INTESTINAL BYPASS IN EXTREME OBESITY. (Eng.) Backman, L.; Johansson, C.; Thoren, P.; Allgen, L. G.; Hallberg, D. (Karolinska Hosp., Stockholm, Sweden). *Acta Med. Scand.* 201(4):285-289; 1977.

Serum tryptophan levels were determined in patients treated with jejunoileostomy for obesity. The frequency of psychiatric symptoms and their possible relation to a low tryptophan level were analyzed, and the serum levels during supplementation with tryptophan were examined. Jejunoileostomy was followed by a decreased level of S-tryptophan (mean preoperative level, 76.4 ± 4.4 μmol/l; 1st yr postoperatively, 45.0 ± 2.0 μmol/l; 2nd yr postoperatively, 42.1 ± 2.9 μmol/l; $p < 0.001$ in both cases); permanently low concentrations were recorded postoperatively in 29 of 52 patients. Patients in the low tryptophan group (i.e., < 36 μmol/l) had a higher rate of weight loss and a higher incidence of electrolyte disturbances ($p < 0.05$) and signs of liver injury ($p < 0.05$). Symptoms of depression and anxiety were slightly more common in patients with low S-tryptophan. The influence of a decreased S-albumin and a deranged amino acid pattern on the non-protein-bound fraction of S-tryptophan needs further investigation. Serum levels of tryptophan rose significantly after p.o. supplementation with 1.2 g L-tryptophan daily for 2 weeks; this dosage was insufficient to normalize a low tryptophan level in the patients who underwent jejunoileostomy.

4875 INTRAVASCULAR HEMOLYSIS, THROMBOCYTOPENIA, LEUKOPENIA, AND CIRCULATING IMMUNE COMPLEXES AFTER JEJUNAL-ILEAL BYPASS SURGERY. (Eng.) Moake, J. L.; Kageler, W. V.; Cimo, P. L.; Blakely, R. W.; Rossen, R. D.; Haesse, W. (Univ. Texas Medical Sch. at Houston, Houston, TX). *Ann. Intern. Med.* 86(5):576-578; 1977.

The case of a 25-yr-old man who developed intravascular hemolysis, thrombocytopenia, and neutropenia 2 yr after jejunoileal bypass operation for obesity is presented. The patient's RBC were coated with complement components (C4/C3) and his serum induced complement-dependent immune lysis of ^{51}Cr-labeled platelets. Serum ^{125}I-Clq binding activity (a measure of the presence of immune complexes) was increased, and serum C4 and C3 hemolytic titers were depressed. Immune complex-mediated complement activation apparently accounted for the blood cell destruction in this patient.

4876 PATTERNS OF HEPATIC MORPHOLOGY IN JEJUNOILEAL BYPASS PATIENTS. (Eng.) Peters, R. L. (John Wesley Hosp., 2826 South Hope St., Los Angeles, CA 90007). *Am. J. Clin. Nutr.* 30(1):53-57; 1977.

The close similarity of the hepatic histological pattern in jejunoileal bypass and in chronic alcoholism is described, and the case reports of three patients are presented. The most common serious hepatic complication of jejunoileal bypass is the development of acute hepatic failure. The case of a 45-yr-old woman with this complication is presented. She developed elevated bilirubin, SGOT, SGPT, and serum albumin levels within 6 months of the operation, and liver biopsies taken over the next 12 months showed progressive increase in hepatic fibrosis and hepatocellular degeneration. The symptoms improved after bowel continuity was restored. Cirrhosis may develop insidiously after the critical 8-month period following bypass. In a 34-yr-old man with this complication, a biopsy at surgery revealed fat but no fibrosis. Over 3 yr later, a routine follow-up liver biopsy showed a fatty cirrhotic liver without acute cellular degenerative changes, alcoholic hyalin, or cellular infiltration. The least common type of liver complication after jejunoileal bypass is one that is not directly related to the bypass operation but rather is further aggravated by it. A liver biopsy 2 yr following bypass in a 47-yr-old woman showed scanty perivenular fibrosis, minimal fat, and no alcoholic hyalin or cell swelling. However, the patient died 20 days later, and autopsy revealed hydropic degenerative changes, early intrasinusoidal collagen, and moderate alcoholic hyalin necrosis as well as cholestasis.

4877 BILE ACID METABOLISM IN ILEOSTOMY PATIENTS. (Eng.) Huibregtse, K.; Hoek, F.; Sanders, G. T. B.; Tytgat, G. N. J. (Dept. Medicine, Wilhelmina Gasthuis, Amsterdam, Netherlands). *Eur. J. Clin. Invest.* 7(2):137-140; 1977.

To investigate bile acid metabolism after ileostomy, ^{14}C-cholylglycine breath tests were carried out in 10 ileostomy patients, and the bile acid and fat content of the 24-hr ileostomy output were determined and compared to the values in 20 healthy controls. The average fecal fat and bile acid excretion were 1.5 g/day and 469 mg/day, resp. The mean cumulative respiratory $^{14}CO_2$ excretion within 8 hr after the administration of ^{14}C-labeled glycocholate was 1.16% (range, 0.2-0.4%); this value was significantly lower than that obtained in controls (1.9%; range, 0.2-5.0% $p<0.025$). No conjugated bile acids or secondary bile acids were detected in the ileostomy fluid in any of the patients. To study to what extent the bile acid composition in the ileostomy bags reflected its *in vivo* composition, midstream ileostomy specimens were collected from four patients and processed immediately. In these samples, a substantial quantity of bile acids was still present in the conjugated form, and after standing at room temperature in the ileostomy bags, the conjugated bile acids disappeared completely by 21 hr. The results show that colonization of the distal small intestine by a modified fecal flora in patients with ileostomy does not result in an enhanced bacterial bile acid deconjugation, and the disturbance of intestinal motility and transit time after removal of the ileocecal valve and colon does not substantially decrease the efficacy of the bile acid reabsorptive capacity of the ileum.

4878 BILE ACID METABOLISM AFTER JEJUNOILEAL BYPASS OPERATION FOR OBESITY. (Eng.) Bruusgaard, A.; Sorensen, T. I. A.; Justesen, T.; Krag, E. (Dept. Clinical Chemistry, Frederiksberg Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 36(6):833-838; 1976.

Duodenal samples of bile acids and bacterial flora were taken from 12 patients before and after jejunoileal bypass operations to determine the relative responses of bile acid metabolism to two types of operative procedure. Type I bypass included 37.5 cm jejunum and 12.5 cm ileum, and type III bypass included 12.5 cm jejunum and 37.5 cm ileum. Duodenal aspirates from prefasted patients were obtained after cholecystokinin-induced (80 Ivy U) gallbladder emptying. Cholic acid turnover was estimated by isotope dilution after administration of ^{14}C-choline directly into the duodenum. The fractional daily turnover of cholic acid increased about fivefold after both types of bypass. However, the cholic acid pool size decreased significantly after the type III bypass, partially as a result of a smaller stimulation of cholic acid synthesis in this procedure. The ratios of cholic to deoxycholic acids and glycine to taurine conjugates in duodenal bile increased after type I, but not after type III, operations. Bacterial flora and the free bile acid pattern did not change significantly. The more severe disturbance of bile acid metabolism after type III bypass may result from insufficient stimulation of bile acid synthesis.

4879 PNEUMATOSIS CYSTOIDES INTESTINALIS. AN ANGIOGRAPHIC FINDING. (Ger.) von Wyttenbach, A.; Kauzlaric, D.; Pedrazzini, A. (Medizinische Abteilung, Ospedale Distrettuale, CH-6600, Locarno, Switzerland). *Fortschr. Rontgenstr.* 126 (6):560-563; 1977.

The angiographic findings of pneumatosis cystoides intestinalis of ischemic origin (PCI) in a 73-yr-old man are presented, and the pathology and etiology of PCI are briefly discussed. Initially, the patient had bloody stools. A barium enema showed typical signs of PCI, with localization in the sigmoid and splenic flexure. Signs of ischemic colitis were present in the descending colon. The patient was given conservative treatment. No clinical changes were observed 2 months later, and a barium enema showed a similar radiological picture. Abdominal angiography revealed severe atherosclerotic changes in the abdominal arteries, with hemodynamically significant stenoses at the exit of the celiac artery, a sacular aneurysm of the abdominal aorta, and occlusion of the inferior mesenteric artery. The authors stress the importance of radiological diagnosis in this disorder and recommend more angiographic studies.

4880 CELLULOSE GRANULOMAS AND THEIR RELATIONSHI TO INTESTINAL OBSTRUCTION. (Eng.) Tinker M. A.; Teicher, I.; Burdman, D. (Queens Hosp. Center 82-68 164th St., Jamaica, NY 11432). *Am. J. Surg.* 133(1):134-139; 1977.

The incidence, origin, and clinical significance of granulomatous peritonitis caused by cellulose foreign bodies were studied. Among 7,500 surgical specimens and autopsies, 45 cases of cellulose foreign body granulomas were identified by light microscopy. The patients had had at least one previous surgical procedure involving the same area. Twenty-seven cases were extraperitoneal. Eighteen were located within the peritoneal cavity, of which 5 were found at autopsy and 13 were identified at laparotomy. Two patients had granulomatous peritonitis, and six had mechanical small bowel obstruction associated with the granulomas. Among 12 surgical specimens from patients who had undergone surgery for intestinal obstruction during the study period, cellulose granulomas were detected in six, suggesting that cellulose foreign body granuloma may be a significant cause of intestinal obstruction. The 45 cases of foreign body granuloma were examined with polarization techniques and by scanning electron microscopy in an attempt to determine the source of the cellulose fibers as either cotton or wood. The origin could not be definitivel established in most cases because of loss of morphologic characteristics. However, fibers were positively identified as wood in 2 of 10 cases examined with scanning electron microscopy, which supports the theory that they were derived from disposable surgical fabrics.

4881 STUDIES OF IDIOPATHIC INTESTINAL PSEUDO-OBSTRUCTION. II. HEREDITARY HOLLOW VISCERAL MYOPATHY: FAMILY STUDIES. (Eng.) Schuffler, M. D.; Pope, C. E., II (Unites States Public Health Service Hosp., P.O. Box 3145, Seattle WA 98114). *Gastroenterology* 73(2):339-344; 1977.

Twelve relatives of a 15-yr-old girl with idiopathic intestinal pseudo-obstruction (IIPO) were studied with esophageal manometry or cine-esophagography to determine whether the disease was genetically transmitted. Four maternal relatives, including the patient's mother, 13-yr-old brother, one aunt, and one of that aunt's children, had mild dysphagia and esophageal motor dysfunction. In addition, the patient's mother and 13-yr-old brother had a flaccid bladder and bilateral ureteral reflux, resp. The brother had abnormal bladder smooth muscle by light microscopy; marked fibroses separating abnormal smooth muscle cells were present. It is concluded that IIPO in this family is secondary to a generalized disease of smooth muscle that is transmitted as a dominant trait of variable expressivity. It is manifested in some family members as a mild disorder of esophageal smooth muscle dysfunction and at times is accompanied by bladder dysfunction. The authors suggest that this form of IPPO be called "hereditary hollow visceral myopathy." Esophageal manometry may be useful for studying the inheritance of this disorder.

4882 COMMON BILE DUCT OPENING INTO A DUODENAL DIVERTICULUM. (Ger.) Mall, K.; Schmidt, M. (Krankenhaus Moabit, Turmstrasse 21, 1000 Berlin 21, W. Germany). *Fortschr. Roentgenforsch.* 125(5):474-475; 1976.

SMALL INTESTINE

Malabsorption

4901 ANEMIA AND INTESTINAL DYSFUNCTION IN FORMER RESIDENTS OF THE CARIBBEAN. (Eng.) Meyers, S.; Schweitzer, P.; Gerson, C. D. (U.S. Walson Army Hosp, Fort Dix, NJ 08640). *Arch. Intern. Med.* 137(2):181-186; 1977.

The problem of differentiating pernicious anemia from tropical sprue in five patients with megaloblastic anemia, vitamin B_{12} deficiency, normal or elevated serum folate levels, and small intestinal dysfunction is discussed. All of the patients were natives of the Caribbean area living in New York City. Achlorhydria, serum anti-intrinsic factor antibody, the severity of small intestinal abnormalities, and post-therapy Schilling tests were helpful in differentiating two patients with pernicious anemia from three with tropical sprue. Achlorhydria was present in the two anemic patients and was not present in two patients with tropical sprue that were tested. Similar results were obtained for anti-intrinsic factor antibody. Post-therapy Schilling test values (without intrinsic factor) were normal (greater than 8%) in the three tropical sprue patients, being 9.1, 13.8, and 8.8%, resp.; in the two anemic patients, these values were 0.1 and 0.50%, resp. Folate levels were within the normal range (5-15 ng/ml) in the two anemic patients, but were elevated in two of the three tropical sprue patients (33.3 and 20 ng/ml, resp.). Abnormalities in jejunal morphology were more dramatic in tropical sprue patients. Dilation of the proximal jejunum was seen in each patient with tropical sprue, whereas in pernicious anemia, small intestinal barium studies were normal.

4902 GLIADIN-INDUCED MIGRATION INHIBITION OF PERIPHERAL LEUKOCYTES BY THE AGAROSE-PLA TECHNIQUE IN PATIENTS WITH CELIAC DISEASE. (Ger.) Douwes, F. R.; Lippmann-Nielsen, I.; Hanke, R. (Me izinische Klinik und Poliklinik der Universitat, Humboldtallee 1, 3400 Gottingen, W. Germany). *Dts Med. Wochenschr.* 102(19):721-724; 1977.

Sensitization to gliadin (100 µg/ml) was studied b the modified leukocyte migration inhibition test i 10 patients with celiac disease (CD), 9 with ulcerative colitis (5 receiving salazosulfapyridine), 9 with terminal ileitis (3 were receiving salazosulfapyridine), 9 with bacterial diarrhea (all were receiving antibiotics), 8 with duodenal and ventricular ulcer, 2 with chronic recurrent pancreatitis, and 4 with colon carcinoma. Following preparation of the leukocyte suspension, 8.0 µl was placed on agar plates with gliadin (10-600 µg/ml) and incubated in a humidity chamber at 37 C for 18 hr, after which time the migration index (MI) was calculated. Patients with CD had a mean MI of 0.72 ± 0.06 (control=1.04 ± 0.11), whereas other patients had a significantly higher MI (0.98-1.13). A quantitative study of the inhibition of migration in five patients with CD showed a close correlation between the MI and the concentration of gliadin that caused inhibition; inhibition was optimum at 100 μg/l. Above 500 μg/ml the viscosity of the medium was so changed that even normal cells could no longer migrate, which indicated that at these concentrations, the function impairment was not induced by soluble lymphokines, but by the antigen and its chemical properties. The positive T-cell response could be abolished by pretreatment of lymphocytes with puromycin (20 μg/ml). After incubation, no active synthesis of MI factor was observed, and leukocytes migrated freely in the agarose, even in the presence of the antigen. The results suggest that cellular immune mechanisms play a role in CD.

4903 A NEW EXPERIMENTAL SYSTEM FOR THE STUDY OF THE PATHOGENESIS OF COELIAC DISEASE.

(Eng.) Hudson, D. A.; Anderson, C. M.; Cooper, B. T. (Dept. Pediatrics and Child Health, Univ. Birmingham, Birmingham, England). *Lancet* 1(8010):511-512; 1977.

A method for the differential removal of epithelial cells from human intestinal tissue specimens is described, and this method was applied to jejunal biopsy specimens from controls and patients with celiac disease. A phosphate-buffered citrate solution (pH 7.4) is used to pretreat the tissue for 15 min before release of the epithelial cells by mechanical agitation. This procedure was usually sufficient to remove all villous epithelial cells, but not the crypt cells; the latter could be removed by a second 15-min incubation ending with further mechanical treatment. Differential removal of epithelial cells from "flat" biopsy specimens from subjects with celiac disease was achieved without modification of this procedure. The epithelial cells were largely released as sheets or aggregations. Dispersal of these sheets revealed that the separated cells retained their characteristic shape with a distinct, regular brush border and basal nucleus. Trypan blue dye exclusion tests indicated that a minimum of 60% of the cells were viable, although in most specimens viability approached 90%. Short-term survival in defined media confirmed the viability. RBC was the major cellular contaminant of the enterocyte suspensions and could be readily removed by centrifugation through a buffered solution of a "Ficoll"/"Triosil" mixture. This system can be used to investigate the differential cytotoxic effects of specific gluten components upon cells from normal subjects and celiac patients.

4904 COELIAC DISEASE WITH MILD MUCOSAL ABNORMALITIES: A REPORT OF FOUR PATIENTS.

(Eng.) Scott, B. B. Losowsky, M. S. (St. James' Hosp., Leeds LS9 7TF, England). *Postgrad. Med. J.* 53(617):134-138; 1977.

Small intestinal biopsies that were neither normal nor completely flat, as found in classical celiac disease, were detected in 17 of 123 patients with suspected malabsorption. In 6 of these 17 patients, there was no apparent cause for the mild mucosal abnormality. Four of these patients were treated with a gluten-free diet, and all responded morphologically and symptomatically. Each of these four patients had jejunal biopsies before treatment that were convoluted, as well as ridged in one case; after treatment, the biopsies were villous. In one case, the patient was given p.o. iron and i.m. vitamin B_{12} simultaneously with the gluten-free diet; the possibility must be considered that the response may have been due to these hematinics rather than to the gluten-free diet. It is concluded that at least three of these four patients had celiac disease in a mild form and that a classical flat biopsy is not a prerequisite for the diagnosis of celiac disease. It is suggested that the criterion for the diagnosis of celiac disease should be the demonstration of an unequivocal improvement of any mucosal abnormality in response to a gluten-free diet or deterioration in response to gluten.

4905 HLA ANTIGEN IN CHILDREN WITH CELIAC DISEASE AND IN CHILDREN WITH INTOLERANCE TO COW'S MILK PROTEINS.

(Fre.) Mougenot, J. F.; Hors, J.; Schmid, M.; Cathelineau, L.; Navarro, J.; Polonovski, C. (Hopital Trousseau, 26, ave. du Dr.-Arnold-Netter, F-75012 Paris, France). *Gastroenterol. Clin. Biol.* 1(6/7):507-514; 1977.

The HLA phenotype of 53 children with celiac disease and of 39 children with intolerance to cow's milk proteins was determined. A microlymphocytotoxicity technique was used to identify 28 alleles at the A and B loci. The distribution of HLA antigens in the patients with cow's milk intolerance was not significantly different from that in normal controls. Of the 38 European patients with celiac disease, 58% had HLA-B8, compared to 17% of European controls. The 15 North African children with celiac disease showed an HLA-B8 frequency of 33%, while normal North Africans were 12% positive. This corresponds with the decrease in frequency of the B8 allele from Northern Europe to Southern Europe to North Africa. This study confirms that the gene complex coding for gluten intolerance is strongly, but not invariably, linked with the B8 locus.

4906 THE ASSOCIATION OF HL-A-B8 AND CHILDHOOD CELIAC DISEASE IN AN ISRAELI POPULATION.

(Eng.) Gazit, E.; Avigad, S.; Zfat, Z.; Efter, T.; Mizrachi, Y.; Rotem, Y. (Chaim Sheba Medical Center, Tel-Hashomer, Israel). *Isr. J. Med. Sci.* 13(4):400-404; 1977.

The frequency of histocompatibility antigens (HL-A) was studied in 33 Israeli children with celiac disease to detemine if HL-A-B8 is associated with celiac disease in Middle Eastern populations (in which the frequency of this antigen is low). HL-A-B8 phenotype was detected in 27.3% of the celiac patients and 7.5% of 395 matched controls (χ^2 for heterogeneity=14.23, $p<10^{-4}$). HL-A typing, especially in children, is advocated both as a diagnostic and a prognostic measure.

4907 DIGESTIVE INTOLERANCE TO COW'S MILK PROTEIN IN THE INFANT. CLINICAL STUDY OF 15 CASES.

(Fre.) Marie, F.; de Menibus, C. H.; LeDosseur, P.; Mallet, E.; Tron, P. (Hopital Charles Nicolle, bd. Gambetta, 76038 Rouen Cedex, France). *Ann. Pediatr. (Paris)* 24(5):383-387; 1977.

Transient intolerance to cow's milk was reported in 15 infants (11 boys, 4 girls), aged 15-80 days. The chief manifestations of the intolerance were weight loss (15 infants), diarrhea (14), vomiting (13), fever (3), and allergy (4, erythema or urticaria). Of the 15 infants, 5 had a familial history of intolerance to cow's milk. The intolerance usually developed very early but in one case it occurred at the age of 68 days. Seven infants went into shock when milk was reintroduced 13-70 days after its exclusion. The infants became pale and developed tachycardia; a drop in arterial pressure associated with vomiting, diarrhea, and dehydration also occurred. In one instance it was accompanied by an urticarial reaction. However, all symptoms of intolerance disappeared gradually when milk was reintroduced 7-14 months later. Systemic jejunal biopsies were not performed due to the young ages and poor condition of the infants. The lymphocyte transformation test was negative in all children.

4908 SOY PROTEIN INTOLERANCE: FOUR PATIENTS WITH CONCOMITANT COW'S MILK INTOLERANCE.

(Eng.) Whitington, P. F.; Gibson, R. (Univ. Wisconsin, Center Health Sciences, 1300 University Ave., Madison, WI 53706). *Pediatrics* 59(5):730-732; 1977.

Four infants with intractable diarrhea due to soy protein intolerance are reported. Each patient developed diarrhea in the first month of life on a cow's milk formula. The diarrhea was unresponsive to dietary management with a soy protein-based formula. Malnutrition was the most prominent feature, and dehydration was also common. The diagnosis of soy protein intolerance was confirmed by challenge with soy protein isolate (200 mg or 2 g), which resulted in diarrhea, vomiting, fever, lethargy, and pale, mucoid stools. Vomiting usually occurred within 15 min of challenge and the diarrhea never persisted past 12 hr after challenge. One patient developed hypotension. Concomitant cow's milk sensitivity was confirmed in each patient by challenge with skimmed milk after documentation of lactose tolerance. A diet devoid of intact soy and cow's milk (a sucrose-casein hydrolysate formula) was well-tolerated in all patients and resulted in rapid weight gain. Oral disodium cromoglycate therapy was ineffective in one trial. Soy protein intolerance should be suspected in infants with diarrhea resistant to therapy with soy based formulas.

4909 MINIMAL BILE ACID MALABSORPTION AND NORMAL BILE ACID BREATH TESTS IN CYSTIC FIBROSIS AND ACQUIRED PANCREATIC INSUFFICIENCY.

(Eng.) Roller, R. J.; Kern, F., Jr. (Univ. Colorado Medica Center, 4200 East 9th Ave., Denver, CO 80220). *Gastroenterology* 72(4):661-665; 1977.

To confirm previous reports that fecal bile acid excretion is increased in children with cystic fibrosis, 1-^{14}C-cholylglycine breath tests were carried out in patients with cystic fibrosis and acquired pancreatic insufficiency, and the fecal bile acid and fat excretion were determined. The patients included 8 cystic fibrosis patients, 10 patients with ileal resections, 9 patients with acquired pancreatic insufficiency, 10 controls wit diarrhea, and 11 healthy subjects. Studies were done when patients were taking pancreatic enzymes (Cotazym) and also when no medication was given. $^{14}CO_2$ excretion in breath was normal in patients with acquired pancreatic insufficiency (normal= 0-4.97% in diarrhea and in healthy controls). $^{14}CO_2$ excretion was significantly lower in the cystic fibrosis patients ($p<0.05$), both with and without Cotazym therapy. Fecal bile acid excretio was slightly elevated in both groups without Cotazym and became normal with Cotazym in patients with acquired pancreatic insufficiency. Steatorrhea was present in both patient groups and improved during Cotazym therapy. Bile acid malabsorption in cystic fibrosis and in acquired pancreatic insufficiency is minimal and probably not clinically important.

4910 BILE ACID MALABSORPTION--A CONSEQUENCE O TERMINAL ILEAL DYSFUNCTION IN PROTRACTED DIARRHEA OF INFANCY.

(Eng.) Balistreri, W. F.; Partin, J. C.; Schubert, W. K. (Univ. Cincinnati Coll. Medicine, Cincinnati, OH). *J. Pediatr.* 89(1 21-28; 1977.

Fecal labeled bile acid excretion was measured in two infants with protracted diarrhea and in contro in order to determine if bile acid malabsorption w responsible for the diarrhea. The controls includ four infants who had undergone ileal resection, fo patients with steatorrhea due to pancreatic or mucosal defects not involving the ileum, and five patients with mild-to-moderate chronic diarrhea but without steatorrhea. The mean fecal excretion of ^{14}C-24-cholic acid in the patients with protracted diarrhea (44.5 ± 13.5%/24 hr) and in the patients who underwent ileal resection (37.8 ± 12.8%) was significantly increased in comparison with that in the patients with steatorrhea (7.5 ± 2.9%) or in those with chronic diarrhea (4.8 ± 1.0%). The rat of mean 24-hr excretion of bile acid to that of a nonabsorbable marker (polyethylene glycol) confirmed the malabsorption of bile acid in the patie with intractable diarrhea or ileal resection; thes results differed significantly ($p<0.05$) from excretion ratios obtained in patients with either steatorrhea or chronic diarrhea. The extent of bile acid loss was not related to the rate of feca fat excretion. There was no direct correlation of fecal weight with the rate of bile acid excretion. The Schilling test of ileal function was abnormal (<1.0% excretion/24 hr) in both the protracted diarrhea and ileal resection patients, whereas it was normal in the other two groups. The results suggest that bile acid malabsorption was involved in the pathophysiology or prolongation of diarrhea in these two infants.

4911 MALABSORPTION IN RELATION TO ABDOMINAL IRRADIATION AND QUADRUPLE CHEMOTHERAPY FOR LYMPHOSARCOMA. (Eng.) Scarpello, J. H. B.; Sladen, G. E. (Royal Hosp., West St., Sheffield S1 3SR, England). *Postgrad. Med. J.* 53(618):209-221; 1977.

The case of a patient with bile acid malabsorption following chemotherapy and abdominal irradiation for lymphosarcoma is reported. The patient, a 58-yr-old man, experienced temporary watery diarrhea after he underwent three courses of chemotherapy (nitrogen mustard, 7.5 mg; vincristine, 2.0 mg, i.v., days 1 and 8; procarbazine, 50 mg b.i.d.; and prednisolone, 10 mg t.i.d., p.o. for 2 weeks) and one course of irradiation (800 rad to the abdomen) for the treatment of stage IV lung and pleural lymphosarcoma. His symptoms commenced during radiotherapy and resolved shortly thereafter. He had remained well and in clinical remission for 9 months when he experienced acute abdominal pain, watery diarrhea, and steatorrhea. The fecal fat averaged 56 mmol/day (normal <21), and fecal bile acids were 3,477 and 2,578 μmol/24 hr on two occasions (normal <880). The patient responded to a low fat diet and treatment with cholestyramine; the patient remains well on this regimen 2.5 yr after the onset of diarrhea, and chemotherapy has been continued. A questionnaire was sent to 32 subjects who had undergone similar treatment for similar pathology; it failed to demonstrate any sustained alteration of bowel function. In addition, nine of these subjects underwent a ^{14}C-glycocholic acid test, and no evidence of interruption of the enterohepatic circulation of bile acids was found. Bile acid malabsorption appears to be a very unusual complication of treatment for cancer and has not been previously reported.

LARGE INTESTINE

4925 WHOLE GUT IRRIGATION: AN INADEQUATE PREPARATION FOR DOUBLE CONTRAST BARIUM ENEMA EXAMINATION. (Eng.) Bakran, A.; Bradley, J. A.; Bresnihan, E.; Lintott, D.; Simpkins, K. C.; Goligher, J. C.; Hill, G. L. (General Infirmary, Leeds LS1 3EX, England). *Gastroenterology* 73(1):28-30; 1977.

Since the method of whole gut irrigation has been claimed to be very effective and convenient in preparing the colon for surgery, its efficacy in the preparation of the bowel for double contrast barium enema examination was assessed in 20 outpatients of similar age, sex distribution, and symptomatology. The patients presented for barium enema examination by a modification of the Malmo double contrast technique, and were randomly allocated to two groups. The "normal" preparation group ate a restricted diet and took a laxative the day before. Immediately before the examination the colon was washed out using colonic lavage. The "irrigation" group omitted the laxative. The colon was cleansed with warmed isotonic saline that was infused down a nasogastric tube until the effluent was clear or 10-12 l had been infused. The average amount infused was 10.5 ± 1.1 l over a mean time of 1.64 ± 0.2 hr. The examinations were performed by one radiologist. Three radiologists (without knowledge of the preparation used) independently assessed all radiographs according to the amount of water and feces remaining, the quality of mucosal coating, the amount of barium present, and terminal ileum filling. When the results of the three radiologists were pooled, mucosal coating and definition were found to be significantly worse in the irrigated patients ($p<0.025$ Mann-Whitney u-test). There were also significant increases in residual water, amount of barium present in the colon, and terminal ileum filling ($p<0.05$) in the irrigated patients, although no difference was noted in the amount of residual feces. Whole gut irrigation is not a satisfactory preparation for double contrast barium enema examination.

4926 AN ULTRASTRUCTURAL STUDY OF OSMIOPHILI IN THE HUMAN RECTUM. (Eng.) Levison, A.; Pennington, C. R.; Hopwood, D. (Ninewells Hosp. and Medical Sch., Dundee, Scotland). *Hist chem. J.* 9(1):77-88; 1977.

Rectal biopsies taken 7 cm above the anal margin from 24 patients with various forms of inflammat bowel disease (9 with ulcerative colitis, 3 with Crohn's disease, and 12 with diarrhea) and from 3 patients with a normal rectum were studied by a prolonged osmication technique. No consistent ultrastructural differences were observed betwee these groups. However, there were striking diffe ences between individual epithelial cells in the same biopsy and between the epithelium and cells of the lamina propria. The Golgi apparatus was demonstrated occasionally in the epithelium and often in the endothelium. Endoplasmic reticulum, perinuclear cisterna, and mitochondria were vari outlined. Striking variations were seen in the deposition of osmium in the endoplasmic reticulu of plasma cells. The underlying mechanism of the different staining patterns is not clear. The findings do not appear to help in the differenti diagnosis of inflammatory bowel disease and do n shed any new light on the underlying pathogenic mechanisms.

4927 CHARACTERIZATION OF A HYPERACTIVE SEGM AT THE RECTOSIGMOID JUNCTION. (Eng.) Chowdhury, A. R.; Dinoso, V. P.; Lorber, S. H. (Dept. Gastroenterology, Temple Univ. Hosp., 340 N. Broad St., Philadelphia, PA 19140). *Gastroent ology* 71(4):584-588; 1976.

Motor wave activity of the colon and rectum was studied in 39 patients with motor disorders of th colon and in 12 controls to investigate the hyper activity at the rectosigmoid junction observed with chronic constipation. Subjects fasted overnight and were given an enema 1 hr before each test. Intraluminal pressure at various levels near the junction was monitored by a triple lumen tube assembly introduced through a sigmoidoscope. Respiration was monitored simultaneously. Hyperactive segments, identified by continuous complex wave activity or superimposed repeated waves, were 1.5-2 cm long and 9-15 cm from the anal verge. The hyperactive segments were not affected by i.v. secretin or cholecystokinin. However, atropine sulfate and glucagon inhibited the hyperactive segments significantly, suggesting that the abnormal activity may be due to continuous discharge of a neurotransmitter that stimulates the muscarinic effector cells. Persistent hyperactivity was observed in 75% of the patients with chronic constipation, including 8/10 patients with irritable colon and 4/5 patients with colonic diverticulosis. Hyperactivity was not present in the controls, and it was observed in only 1/15 patients with colon disorders who were not suffering from chronic constipation. These studies suggest that hyperactivity at the rectosigmoid junction may be either a cause or effect of chronic constipation, but not an effect of any underlying disorder.

4928 APPROACH TO SCREENING AND DIAGNOSIS IN COLORECTAL CANCER. (Eng.) Winawer, S. J.; Sherlock, P. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021). *Semin. Oncol.* 3(4):387-397; 1976.

The screening and diagnosis of colorectal cancer are discussed. Persons with previous history of colon polyps or colon cancers are at highest risk for a new colon cancer within 5 yr of the index cancer and should have a repeat air-contrast barium enema and a colonoscopy to clear the colon thoroughly of additional lesions at 2 months after initial treatment. Following these procedures, they should be reexamined thoroughly every 2-3 yr and have Hemoccult slide-testing and sigmoidoscopy done annually. Patients with underlying premalignant colon diseases such as ulcerative colitis, granulomatous colitis, and any one of the genetically acquired polyposis syndromes must be followed, primarily by endoscopic and cytological techniques. Radiologic examinations can supplement these. Sigmoidoscopy, with rectocolonic cytological lavage, should be done every 6 months and colonoscopy with cytological lavage once a year in the asymptomatic patient with polyposis or ulcerative colitis. Following any subtotal resection, frequent sigmoidoscopy with cytological lavage is important. Patients with family histories of single or multiple primary colon cancers or multiple carcinomas in different anatomic sites and relatives of patients with polyposis syndromes or juvenile polyps should have an annual sigmoidoscopy and Hemoccult slide testing. If the latter is positive, they should have barium enema with air contrast, followed by colonoscopy for complete evaluation of the colon. Periodic screening should probably begin by the age of 20 yr. If these patients are shown to have developed the polyposis syndromes, they must be followed more aggressively, as suggested for patients with underlying premalignant diseases. Asymptomatic persons over the age of 40 yr should be screened in the same manner as asymptomatic patients with significant family histories. Any patient with a positive Hemoccult slide test and no demonstrated colon pathology should have an upper gastrointestinal and small bowel series done.

4929 TRITIATED THYMIDINE INCORPORATION INTO EPITHELIAL CELLS OF NORMAL-APPEARING COLORECTAL MUCOSA OF CANCER PATIENTS. (Eng.) Maskens, A. P.; Deschner, E. E. (Hopital Universitaire St. Pierre, B 3000, Louvain, Belgium). *J. Natl. Cancer Inst.* 58(5):1221-1224; 1977.

A radioautographic analysis of the number and position of labeled epithelial nuclei after *in vitro* incorporation of tritiated thymidine ([^{3}H]TDR) was carried out with 30 specimens of histologically normal colorectal mucosa from 13 patients with rectal or sigmoid cancer and 13 controls. A higher mean labeling index was found in the cancer than in the control group (9.8% ± 1.2 and 7.9% ± 0.9, resp.). Because of wide individual variations, this difference was not statistically significant. However, a highly significant upward shift of the proliferating cell compartment was observed in the cancer group, resulting in a specific modification of the [^{3}H]TDR labeling pattern in 6 of 17 specimens. DNA synthesis predominated in the middle or middle and upper thirds of the crypts of Lieberkuhn, rather than in the lower third as observed in controls. The patchy alteration of epithelial cell renewal frequently accompanying colorectal cancer suggested a defect in the regulatory control mechanism. This *in vitro* [^{3}H]TDR incorporation assay could provide a valuable discriminatory parameter in studies of high-risk populations.

4930 HYDROLYTIC ENZYMES IN COLORECTAL CANCER. (Eng.) Double, J. A.; Cooper, E. H.; Goligher, J. C. (Dept. Experimental Pathology and Cancer Res., Univ. Leeds, Leeds LS2 9NL, England). *Biomedicine* 27(1):11-13; 1977.

The activities of five hydrolytic enzymes, sulfatase A/B, sulphatase C, β-glucuronidase, acid phosphatase, and alkaline phosphatase, were measured in 22 patients with metastatic colorectal cancer and in 16 patients treated for colorectal cancer with no evidence of recurrence. The mean activities of sulfatase A/B, sulphatase C, β-glucuronidase, acid phosphatase, and alkaline phosphatase among all 38 patients were 0.30 ± 0.29, 7.48 ± 4.70, 2.89 ± 2.46, 51.20 ± 19.49, and 25.59 ± 14.92 μmol substrate hydrolyzed/min/g protein, resp.; the corresponding ranges were 0.09-1.64, 0.32-21.20, 0.48-11.10, 7.30-101.30, and 1.30-69.60 μmol/min/g, resp. There were no significant differences between the enzyme activities in patients with metastatic tumors and in patients with localized tumors. It is concluded that there are wide variations in the levels of hydrolytic enzymes in colorectal cancer. There are patients who might benefit from treatment with tailor-made enzyme activated anti-tumor agents.

4931 UNDESCRIBED TOXIN IN PSEUDOMEMBRANOUS COLITIS.

(Eng.) Larson, H. E.; Parry, J. V.; Price, A. B.; Davies, D. R.; Dolby, J.; Tyrrell, D. A. J. (Northwick Park Hosp. and Clinical Res. Center, Harrow, Middlesex HA1 3UJ, England). *Br. Med. J.* 1(6071):1246-1248; 1977.

The etiology of pseudomembranous colitis was studied in a 12-yr-old girl who developed colitis after a short course of p.o. penicillin and in five other patients with pseudomembranous colitis. The patient experienced intermittent colicky abdominal pain, diarrhea, and vomiting after she had taken 16, 250-mg doses of phenoxymethylpenicillin over 4 days. She had no history of adverse reaction to the antibiotic before or after the illness. Conventional scratch, intradermal, and patch skin tests with benzylpenicillin and with a solution made from the patient's own tablets gave negative results. Electron microscopy of negatively stained grids prepared from ultracentrifuged and immune-precipitated stool suspension failed to show virus particles, but thin sections of colonic exudate fixed in Karnovsky's fixative did show spherical, membrane-bound, virus-like particles of 40-nm in diameter. Although no pathogenic bacteria, mycoplasmas, or viruses were found in the patient's feces, a toxin was found in tissue cultures inoculated with fecal suspensions. Its cytopathic effect had a characteristic pattern, occurring diffusely and simultaneously throughout the cell sheet, progressing to a maximum at 48 hr. Cells became rounded and refractile. This toxin was also found in specimens from four of five other patients with pseudomembranous colitis, but not in six specimens obtained from patients with diarrhea of other etiologies. The toxin was completely inactivated by heating at 56 C for 30 min, but was not restored by the addition of fresh guinea pig complement. The cytopathic effect in mouse Y-1 adrenal cells did not resemble that of *Escherichia coli* enterotoxin. It appeared to be a heat-labile substance with a molecular weight of over 6,000. The titer of the toxin in the 12-yr-old girl was 1/1,000; it was 1/5,000 during the acute phase of illness, 1/100 while her symptoms were improving, and negative (1/5) 1 month after discharge. Pseudomembranous colitis may be caused by a bacterial toxin.

4932 INCIDENCE OF ANTIBIOTIC-RELATED DIARRHOEA AND PSEUDOMEMBRANOUS COLITIS. A PROSPECTIVE STUDY OF LINCOMYCIN, CLINDAMYCIN AND AMPICILLIN.

(Eng.) Robertson, M. B.; Breen, K. J.; Desmond, P. V.; Mashford, M. L.; McHugh, A. M. (Dept. Medicine, Univ. Melbourne, Melbourne, Australia). *Med. J. Aust.* 1(8):243-246; 1977.

An existing intensive drug-monitoring system was used to study the occurrence of pseudomembranous colitis and diarrhea in 100 patients treated with lincomycin and clindamycin. An equal number of matched patients treated with ampicillin were also studied. The incidence of diarrhea was 11% in the lincomycin-clindamycin group and 8% in the ampicillin group. One patient developed pseudomembranous colitis associated with two prolonged courses of lincomycin therapy. The results suggest that the risks associated with the use of lincomycin are acceptable if the drug is given for the approved specific indications.

4933 DIVERTICULAR DISEASE OF THE COLON. (Ge

Glauser, R.; Filippini, L. (Medizinisch
Klinik, Kantonsspital, Spitalstrasse, CH-6004-Lu
Switzerland). *Dtsch. Med. Wochenschr.* 102(20):7
759; 1977.

The diagnostic results of 100 patients with dive
ticular disease of the colon are presented. Eig
six patients were between 60 and 90 yr of age.
chief symptoms were abdominal pain, irregular st
fever, leukocytosis, and bleeding from the large
testine. In all cases, the diagnosis of diverti
losis of the large intestine with localization i
the sigmoid flexure was made radiologically or o
atively, and a rectosigmoidoscopy was performed
the majority of cases. Of the 100 patients, 23
were hospitalized with a diagnosis of diverticul
or diverticulitis. Inflammatory stenoses were
found in 14 patients, and 4 had mechanical ileus
Perforation subsequent to diverticulitis was see
in five patients, two of whom required surgery.
One patient had a colovesicular fistula, which h
to be treated surgically. Forty-four patients (
of 36 patients with diverticulosis with inflamma
symptoms and 26 of 64 diverticulitis patients) h
anal hemorrhage, and these were classified as ma
(31) and microhemorrhaging (13). Macrohemorrhag
occurred in 14 diverticulosis and 17 diverticuli
patients. Five patients required blood transfus
All patients were given conservative treatment c
sisting of a diet rich in roughage.

4934 PATHOGENESIS OF BLEEDING COLONIC DIVER CULOSIS.

(Eng.) Meyers, M. A.; Alons
D. R.; Gray, G. F.; Baer, J. W. (Dept. Radiology
New York Hosp., 525 E. 68th St., New York, NY 10
Gastroenterology 71(4):577-583; 1976.

Arteriographic and microangiographic techniques
histological sectioning were used to locate and
observe colonic diverticula in 10 patients with
bleeding colonic diverticulosis and in 20 contr
patients. In control colonic diverticula, the
rectum passes through the connective tissue sept
from the serosa to the submucosa. In colonic
diverticulosis, the cause of bleeding was found
be asymmetric rupture of the vas rectum either a
the dome of the diverticulum or at its antimesen
margin. The lesion was frequently associated wi
eccentric intimal thickening and thinning of the
media and duplication of the internal elastic la
These changes were not observed in control diver
ticula. It is suggested that in bleeding coloni
diverticulosis, the vessel wall responds to repe
injury from within the colon, resulting in the
observed structural changes and subsequent weake
of the artery prior to rupture.

4935 ON THE NATURE AND ETIOLOGY OF VASCULAR ECTASIAS OF THE COLON. DEGENERATIVE

LESIONS OF AGING. (Eng.) Boley, S. J.; Sammartano, R.; Adams, A.; DiBiase, A.; Kleinhaus, S.; Sprayregen, S. (Montefiore Hosp. and Medical Center, 111 East 210th St., New York, NY 10467). *Gastroenterology* 72(4):650-660; 1977.

Right colons, resected from patients with either suspected vascular lesions of the cecum or colonic carcinomas, were studied to gain information on the etiology and significance in gastrointestinal bleeding of these lesions, particularly in elderly patients. Colons from 19 patients with clinical and angiographic diagnoses of cecal vascular lesions were studied by injection and clearing, and by histological sections. In all injected specimens, one or more mucosal vascular ectasias were identified. The mucosal lesions appeared to be secondary to dilated tortuous submucosal veins that were the more prominent feature and were often present without the mucosal ectasia. This finding suggests that ectasias are caused by chronic, intermittent, low grade obstruction to submucosal veins with dilation and tortuosity initially of submucosal veins, then of venules, capillaries, and arteries of the mucosal vascular unit. Ultimately, precapillary sphincters lose their competency, producing small arteriovenous communications. The concept that ectasias are degenerative lesions was evaluated by studying 15 right colons resected for carcinoma with no history of bleeding. Mucosal ectasias were identified in four colons and submucosal ectasias in eight. These investigations suggested that these lesions (1) are vascular ectasias developing as a degenerative process of aging, (2) are present with or without bleeding in a significant portion of the population over 60 yr of age, (3) are multiple more often than single, and (4) may represent the commonest cause of major lower intestinal bleeding in the elderly.

LARGE INTESTINE

Ulcerative Colitis

4958 THE RADIOLOGICAL DIFFERENTIATION BETWEEN ULCERATIVE AND GRANULOMATOUS COLITIS BY DOUBLE CONTRAST RADIOLOGY. (Eng.) Laufer, I.; Hamilton, J. (Hosp. Univ. Pennsylvania, Philadelphia, PA 19104). *Am. J. Gastroenterol.* 66(3):259-269; 1976.

Double contrast radiology was used to detect the early changes of colitis and to differentiate between ulcerative and granulomatous colitis in 50 consecutive patients with radiologically diagnosed nonspecific colitis. Patient preparation involved the administration of clear fluids for 24 hr, a mild laxative the evening before examination, and a cleansing enema of 2,000 cm^3 tap water 1 hr before examination. A suspension consisting of a 3:2 mixture of Barosperse and Interopaque was used for the double contrast examination. Barium was introduc
to the splenic flexure and was followed immediate
by the insufflation of air with rotation of the
patient to ensure adequate coating and distention
of all parts of the colon and rectum. The differ
tial diagnosis of ulcerative colitis, which was
successful in 23 patients, included the following
features: granular mucosa (due to edema and supe
ficial erosions), diffuse rectal disease (punched
out ulcers rarely seen in the rectum), continuous
disease (showing no normal mucosa in an involved
segment and no normal segments of bowel interveni
between two diseased segments), a normal terminal
ileum, and discrete ulcers invariably occurring o
a background of abnormal, granular mucosa. In co
trast, granulomatous colitis (which was successfu
diagnosed radiologically in 27 patients) was mani

fested by the absence of a granular appearance of the mucosa, a tendency towards discontinuous disease (skip lesions or discrete ulceration on the normal mucosa), involvement of the terminal ileum (frequently in continuity with disease in the cecum and ascending colon), and punched out rectal ulcers on a background of normal mucosa. Whereas the radiological assessment of rectal disease in ulcerative colitis was very accurate because of the diffuse nature of the disease, minimal or patchy disease was difficult to detect in granulomatous colitis. Endoscopic abnormalities were found in 13 of 27 patients with granulomatous colitis but were detected radiologically in only 8 of these patients. Nevertheless, in no case did the overall radiological diagnosis conflict with endoscopic or pathological information. The absence of indeterminate cases in this series is ascribed to the detail demonstrable by the double contrast technique and the inclusion of early cases whose appearance was not modified by treatment or by recurrent exacerbations and remissions.

4959 TWO-STAGE SURGICAL TREATMENT OF ACUTE COMPLICATED ULCERATIVE COLITIS: INDICATIONS, OBSERVATIONS, AND RESULTS.

(Ger.) Ewerwahn, W. J.; Winkler, R. (Chirurgische Universitats- und Poliklinik, Martinistrasse 52, 2000 Hamburg 20, W. Germany). *Dtsch. Med. Wochenschr.* 102(23):860-865; 1977.

A new two-step surgical procedure for the management of toxic megacolon in patients with ulcerative colitis is described, and results obtained in 14 patients are presented. The first stage consists of definitive multiple enterostomy and fistulization. Definitive proctocolectomy is performed in a second stage, during remission. Of 14 patients who underwent primary multiple enterostomies, only 3 died: 1 immediately after surgery, 2 others after 54 and 60 days. By comparison, the postoperative mortality was 100% in a group of 16 patients who underwent one-stage proctocolectomy. The two-stage procedure is indicated if, after 48-72 hr of conservative treatment, there is no response. Its indications should be extended to all acute cases requiring operation.

4960 PLASMA CELL ALTERATIONS IN ULCERATIVE COLITIS. AN ELECTRON MICROSCOPIC STUDY.

(Eng.) Gebbers, J. O.; Otto, H. F. (Inst. Pathology, Univ. Hamburg, Martinistrasse 52, D-2000 Hamburg 20, W. Germany). *Pathol. Eur.* 11(4):271-279; 1976.

Colon biopsies from 37 young patients with active ulcerative colitis (UC) were investigated by electron microscopy, with special regard to the inflammatory infiltrate of the lamina propria mucosae. The inflammatory infiltrate in UC was characterized by an accumulation of lymphocytes, macrophages, and plasma cells, with a close topographical relation existing between the plasma cells and other inflammatory cells. The plasma cells lost their characteristic oval shape within the infiltrate. The outer membranes were often multiangular and in close relation to other surface membranes or showed short extrusions that were in contact with other cells. In particular, the plasma cells were characterized by their highly developed rough endoplasmatic reticulum (RER). Frequently, plasma cells were seen with extensive dilated and grotesque deformed RER, which was electron lucent or contained only some flocculent material. The density of ribosomes and mitochondria was decreased, and the surface membranes were often not detectable. These cells represented different states of agony and cell death. The frequent occurrence of Russell bodies, Mott cells, and necrobiotic plasma cells was considered to be a morphological expression of pathological alterations of these cells and could be the morphological expression of an imbalance of the local immunoglobulin system in UC.

4961 ANTI-COLON ANTIBODIES IN ULCERATIVE COLITIS. A CLINICAL STUDY.

(Eng.) Marcussen, H. (Medical Dept. P, Div. Gastroenterology, Rigshospitalet, Blegdamsvej 9, DK-2100 Copenhagen O, Denmark). *Scand. J. Clin. Lab. Invest.* 36(6): 763-767; 1976.

Various clinical parameters of ulcerative colitis were examined in 141 patients for possible correlation to the presence of circulating anticolon mucosal antibodies. The parameters were age, sex, duration of illness, type of course, degree of involvement, extracolonic hypersensitivity, and family history of allergies, ulcerative colitis, or symptoms of ulcerative colitis. The female:male ratio was 1.46:1. Some clinical signs of hypersensitivity were observed in 30% of the patients, and 20% of the patients had circulating anticolon antibodies. Although women comprised most of the patients with antibodies (2.63:1), none of the clinical factors, including sex and age, could be statistically correlated with the presence of antibodies. The appearance of anticolon antibodies is probably a secondary autoimmune response to tissue damage and is of little value in the clinical classification of ulcerative colitis.

4962 LYMPHOCYTOTOXIC AND RNA ANTIBODIES IN INFLAMMATORY BOWEL DISEASE: A COMPARATIVE STUDY IN PATIENTS AND THEIR FAMILIES.

(Eng.) Korsmeyer, S. J.; Williams, R. C., Jr.; Wilson, I. D.; Strickland, R. G. (Univ. New Mexico Sch. Medicine, Albuquerque, NM 87131). *Ann. N.Y. Acad. Sci.* 278:574-585; 1976.

The recent observation of a significant familial occurrence of lymphocytotoxic antibodies (LCA) and antibodies to double-stranded RNA (αRNA) in systemic lupus erythematosus provided the basis for studies of LCA and αRNA in patients with chronic inflammatory bowel disease (IBD) and their families. LCA or αRNA were found in 60% of 23 probands with inflammatory bowel disease (either ulcerative colitis or Crohn's disease) and in 40% of their 90 family members. The combined prevalence of these antibodies in 69 control subjects (unrelated to probands) was only 7%. LCA prevalence was increased in both ulcerative colitis and Crohn's disease probands and relatives; αRNA were present only in Crohn's disease probands and relatives. The prevalence of LCA was significantly greater in close household contacts and nonconsanguineous relatives of IBD probands (40% and 50%, resp.) than among nonhousehold contacts or consanguineous relatives (19% and 24%, resp.); a similar trend was noted with respect to αRNA in Crohn's disease relatives. However, LCA and αRNA were more frequently observed in nonhousehold contacts and consanguineous relatives of IBD probands than in control subjects. There was no correlation between the expression of LCA and αRNA among Crohn's disease probands or their families. The antibody class of αRNA was the same in Crohn's disease probands and their positive family members. The significant occurrence of LCA and αRNA in patients with IBD supports the hypothesis that an environmental agent is important in the pathogenesis of Crohn's disease and ulcerative colitis. The increased prevalence of both antibodies in unaffected family members of IBD probands, particularly in close household contacts, may indicate the horizontal transmission of an infectious agent within these families. However, the fact that LCA and αRNA were also more frequent in consanguineous relatives without close household contact than in controls suggests that a genetic component may be operative in the expression of these antibody responses within the families of IBD probands.

4963 BILE ACID METABOLISM AND VITAMIN B_{12} ABSORPTION IN ULCERATIVE COLITIS. (Eng.)

Lenz, K. (Medical Dept. P., Div. Gastroenterology, Rigshospitalet, Blegdamsvej 9, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 36(6):769-775; 1976.

The effect of ulcerative colitis in the large intestine upon bile acid and vitamin B_{12} absorption in the small intestine, particularly the distal ileum, was investigated in 24 nonoperated patients. Bile acid and vitamin B_{12} absorption was also studied in 10 patients who had a colectomy followed by an ileostomy. Meal-stimulated duodenal bile acid concentrations were abnormally low in 13/24 nonoperated patients, and they decreased with increasing activity of the disease. Two of six colectomized patients had below-normal bile acid concentrations. The glycine/taurine ratio was normal in all but three cases, and deconjugated bile acids in the duodenum were not found in any of the patients. The cholylglycine-1-^{14}C breath test and fecal analysis showed normal ^{14}C levels in the breath in all but one of the nonoperated patients, but fecal output was related to disease activity. ^{14}C output in the breath was normal in the operated patients, but the levels in the ileal discharge were very high (15%-81%). Only five patients showed vitamin B_{12} malabsorption. These results indicate that bile acid absorption in the small intestine is disrupted by ulcerative colitis in the large intestine. Abnormally elevated levels of free bile acids in the ileal effluent of patients with a colectomy may indicate abnormal intestinal flora or a rapid intestinal transit time.

4964 AMYLOIDOSIS AND INFLAMMATORY BOWEL DISEASE

(Eng.) Shorvon, P. J. (St. Thomas' Hosp., Lambeth Palace Rd., London, SE1, England). *Am. J. Dig. Dis.* 22(3):209-213; 1977.

The literature concerning amyloidosis associated with inflammatory bowel disease is reviewed. Only 42 cases have been reported, and 33 of these are included in the review. Only 25 cases can be used as indisputable evidence to support the tenet that amyloidosis is a complication of inflammatory bowel disease. Of the 33 patients, 15 had ulcerative colitis; however, 9 of these were subsequently noted to have features of Crohn's disease rather than colitis. Thus, there is no clear evidence of amyloidosis complicating ulcerative colitis, but it seems to be a serious consideration in Crohn's disease. Of the patients, 24 were male, and the average age of onset of inflammatory bowel symptoms was 28 yr (range, 13-70 yr). The duration of disea before the diagnosis of amyloidosis was 1-20 yr, averaging 10 yr. Prolonged "extrabowel" suppuratio occurred in 23 patients. There seemed to be no association between the development of amyloidosis and steroid administration. In 25 cases, the ileum was affected by inflammatorv bowel disease, indicating that the rich lymphoid structures draining the bowel around the ileum were responsible for the development of amyloidosis. Of the patients in whom inflammatory bowel disease was diagnosed before death, seven survived less than 1 yr after the amyloid deposits were discovered, three survived 1-2 yr, one survived 14 yr, and seven were still alive at this report (1 surviving on renal dialysis). A prospective systematic study of amyloidos in a large number of patients with inflammatory bowel disease is needed.

4965 TOXIC DILATATION OF THE COLON. (Ger.)

Seppelt, U.; Hantschmann, H. (Abteilung fur Allgemeinchirurgie im Zentrum Operative Medizin I, Christian-Albrechts-Universitat Kiel, D-2300 Kiel, W. Germany). *Z. Gastroenterol.* 15(1):21-28; 1976.

General clinical, therapeutic, and prognostic aspects of toxic dilatation of the colon in ulcerati colitis are described with respect to 12 operated patients. The duration of the ulcerative colitis anamnesis varied from 3 months to 4.5 yr. Three patients developed toxic dilatation of the colon during the first manifestation of ulcerative colitis, but it occurred during the second or later recurrences in the others. The duration of the la recurrence of ulcerative colitis, i.e., the one th led to toxic dilatation, ranged from 6 days to 12 weeks. Surgery consisted of primary ileostomy and subsequent colectomy (3 cases), primary colectomy with simultaneous ileostomy (3), or coloproctectom (6). Three patients survived; all three were operated on within the first 10 days after manifestati of the recurrence of ulcerative colitis and within 4 days after the development of toxic dilatation. All other patients died of septic complications; six patients died of peritonitis sepsis within the first 2 postoperative weeks. The patients who die later developed protracted sepsis, stress ulcer, hemorrhage, or perforation of the abscess. The prognosis can be probably improved by early colostomy with double ileostomy prior to perforation.

4966 TREATMENT OF TOXIC MEGACOLON: A COMPARATIVE REVIEW OF 29 PATIENTS. (Eng.) Hartong, W. A.; Arvanitakis, C.; Skibba, R. M.; Klotz, A. P. (Kansas Univ. Medical Center, Rainbow Blvd. at 39th St., Kansas City, KS 66103). *Am. J. Dig. Dis.* 22(3):195-200; 1977.

A review of 29 patients with toxic megacolon complicating ulcerative colitis was undertaken to compare the results of medical and surgical treatment, to determine the optimal timing for surgical intervention, and to identify possible precipitating factors. Twenty-one patients were treated medically with nasogastric suction, steroids, parenteral fluids, blood transfusions, and antimicrobial agents. Of these, 11 showed improvement by subjective and objective criteria and 10 failed to respond. Sixteen patients were treated surgically. This group comprised eight patients who failed to respond to medical treatment and eight treated surgically alone. Total proctocolectomy with ileostomy was performed in eight and subtotal colectomy and ileoproctostomy in eight with subsequent proctectomy and ileostomy in six patients. Six of eight patients treated primarily surgically improved, and two (25%) died. Seven of eight patients treated surgically after failure of medical trial showed definite postoperative improvement, and one failed to do so. Those who were operated on within the first 48-72 hr after the diagnosis of toxic megacolon responded uniformly well. Anticholinergics, opiates, barium enema, and colonoscopy were identified as possible precipitating factors in 70% of cases. The results indicate that early surgical therapy in toxic megacolon is associated with better results than medical therapy ($p<0.025$). Although intensive, optimal medical therapy plays a significant role in the management of toxic megacolon, failure to induce rapid improvement within 48-72 hr indicates definitive surgical treatment.

4967 URETERAL STENOSIS DUE TO RETROPERITONEAL FIBROSIS IN ULCERATIVE COLITIS. (Fre.) Girodet, J.; Mignon, M.; Bonfils, S. (Hopital Bichat, 170, boulevard Ney, F-75018 Paris, France). *Gastroenterol. Clin. Biol.* 1(4):361-364; 1977.

A rare case of ureteral stenosis is reported in a 41-yr-old man who had been suffering from repeated attacks of ulcerative colitis for 5 yr. Surgery revealed severe lesions of the left colon associated with a retroperitoneal fibrosis in which the left ureter was embedded. After the ureter was freed, a colectomy with an ileorectal anastomosis was performed. The clinical recovery was uneventful. Although local fibrosis is rarely reported in ulcerative colitis, its incidence may be underestimated and i.v. urography should be used more routinely in preoperative patients.

4968 ULCERATIVE COLITIS: CYTOLOGIC AND HISTOCHEMICAL CORRELATIONS. COMMENTARY ABOUT THE DEVELOPMENT OF A CASE. (Spa.) Mate Jimenez, J.; Moreno Otero, R.; Pajares Garcia, J. M.; Perez Cuadrado, S.; Martinez Raposo, A. (Gran Hospital del Estado, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 69(5):651-656; 1977.

4976 FINE NEEDLE BIOPSY OF THE PANCREAS. (Eng.) Frederiksen, P.; Thommesen, P.; Skjoldborg, H. (Univ. Inst. Pathology, Municipal Hosp., 8000 Aarhus, Denmark). *Scand. J. Gastroenterol.* 36(6):785-791; 1976.

Fine needle aspiration biopsy of the pancreas was performed during surgery in 60 patients with symptoms such as occlusive jaundice or upper abdominal pain. Preoperative and peroperative examinations raised a suspicion of malignancy in 45 patients that was usually suggested by the presence of a palpable mass in the pancreas. The malignant diagnoses were supported by aspiration biopsies in 27 cases. Further examination of the remaining 18 patients revealed that the suspicious mass was due to either penetrating gastroduodenal ulcers or pancreatitis. The final clinical diagnoses showed that aspiration cytology had given only one false-positive and a few false-negative results and, therefore, should be used in conjunction with other diagnostic procedures.

4977 THE SPECTRUM OF RADIOGRAPHIC FEATURES OF ABERRANT PANCREATIC RESTS INVOLVING THE STOMACH. (Eng.) Kilman, W. J.; Berk, R. N. (Univ. Texas Southwestern Medical Sch. at Dallas, 5323 Harry Hines Blvd., Dallas, TX 75235). *Radiology* 123(2):291-296; 1977.

The radiologic features of 20 cases of pathologically confirmed heterotopic pancreatic tissue involving the stomach were studied. The aberrant rests were located in the gastric antrum in all cases, including the prepyloric area. The tissue was in the antrum in 13 cases, in the prepyloric region in 6 cases, and in the pyloric canal in 1 case. In all patients, the heterotopic tissue was located either on the greater curvature or on the posterior wall of the stomach. In all but one of the cases, a definite mass was identified by the upper gastrointestinal examination. In 12 cases, the mass had the broad base and smooth surface characteristic of an extramucosal intramural tumor. In eight cases, the lesion appeared to be sessile, with the narrow base typical of a gastric polyp. In every case, the surface of the aberrant pancreatic tissue was smooth. The mass was less than 1.0 cm in diameter in five cases, between 1 and 2 cm in six cases, and greater than 2 cm in eight cases. Nine cases showed umbilication or a central niche, but only four of these niches were barium-filled, permitting specific diagnosis of heterotopic pancreatic tissue. The umbilication in the other five was large in proportion to the size of the mass, resembling a healing gastric ulcer or an ulcerating mural tumor. Aberrant pancreatic tissue in the stomach produces a broader spectrum of radiographic findings than had been thought.

4978 FATE OF ORALLY INGESTED ENZYMES IN PANCREATIC INSUFFICIENCY: COMPARISON OF TWO DOSAGE SCHEDULES. (Eng.) DiMagno, E. P.; Malagelada, J. R.; Go, V. L. W.; Moertel, C. G. (Mayo Clinic, Rochester, MN 55901). *N. Engl. J. Med.* 296 (23):1318-1322; 1977.

To assess the fate and efficacy of p.o. ingested enzymes in pancreatic insufficiency, pancreatin wa administered to six patients by two schedules (8 tablets with a standard meal or 2 tablets hourly). In six normal controls, duodenal enzyme activity was quantified and inactivation of ingested enzyme was related to gastric and duodenal pH; in the six patients malabsorption was measured by fecal-balar studies. Postprandially, gastric pH was similar i controls and patients, <4.0 after 40 min. Duodena pH in pancreatic insufficiency declined to approximately 4.0 after 100 min, lower than in controls ($p<0.05$). Approximately 22% and 8% of trypsin anc lipase activity, resp., ingested with either schec were delivered to the ligament of Treitz. Prandia ministration was as effective as hourly administra in decreasing steatorrhea and perhaps more effecti in abolishing azotorrhea. The authors recommend t prandial administration of pancreatin for the trea ment of pancreatic insufficiency.

4979 ENZYME REPLACEMENT THERAPY OF EXOCRINE CREATIC INSUFFICIENCY IN MAN: RELATION BETWEEN IN VITRO ENZYME ACTIVITIES AND IN VIVO PO TENCY IN COMMERCIAL PANCREATIC EXTRACTS. (Eng.) Graham, D. Y. (Baylor Coll. Medicine, 1200 Moursu Ave., Houston, TX 77030). *N. Engl. J. Med.* 296(2 1314-1317; 1977.

Sixteen pancreatic extracts (capsules, tablets, a enteric-coated tablets) were assayed for enzyme a tivities, and the relation between the *in vitro* a tivities and *in vivo* potency was evaluated in six patients with steatorrhea secondary to chronic ex crine pancreatic insufficiency. Lipase activity ranged from 10 to 3,600 U/U, with 11 preparations containing <600 U/U. The preparations with the highest lipase activities were Ilozyme, 3.600; Ku zyme HP, 2,330; Festal, 2,073; Cotazym, 2,014; an Viokase, 1,636 U. Lipase activity *in vitro* corre ated with potency *in vivo* for tablets and capsule with tablets and capsules being effective in reducing steatorrhea by 56.1% ± 9% and 48.6% ± 10%, resp., ($p<0.001$). Enteric-coated tablets were less effective (20% ± 13% reduction, $p<0.02$). Th longer the gastric pH remain ≥ 4.0 ($r=0.915$, $p<0.0$ and the higher the average duodenal pH ($r=0.966$, $p<0.01$), the more marked the reduction in steator rhea.

986 ACUTE PANCREATITIS--A FIVE-YEAR REPORT. (Ger.) Rosahl, W.; Honisch, N. (II. Med-
zinische Klinik, Bezirkskrankenhaus, Auenweg 38,
DR-45 Dresden, E. Germany). *Dtsch. Gesundheitsw.*
2(22):1037-1040; 1977.

herapeutic results achieved in 184 patients with
cute pancreatitis are presented. According to
ummerle's grading, 105 patients were in grade I,
3 in grade II, and 6 in grade III. Diseases of
he bile duct were seen in 99 cases. Fourteen pa-
ients had had a cholecystectomy for cholelithiasis.
epending on grade, therapy consisted of relief by
astric probe for several days, atropinization,
.v. infusion, tetracycline or ampicillin treat-
ent, and, in 142 cases, Contrykal therapy for 3-6
ays. Interim surgery was performed on only 56
atients who developed complications despite an
nitial improvement. Cholelithiasis, choledocholi-
hiasis, and stenosis of Oddi's sphincter were
ound in most of these patients upon surgery. The
verall mortality was 10/184; 7 of these patients
ere >60 yr old. The mortality was 3/95 in grade I
pancreatitis was only a secondary condition to
ore serious diseases in all 3); 3/73 in grade II,
nd 4/6 in grade III (the cause was total pancre-
tic necrosis in 3). The results of interim sur-
ery were largely satisfactory. The prognosis of
cute hemorrhagic pancreatitis was unfavorable
egardless of therapeutic method.

987 GLUCAGON LEVELS IN ACUTE PANCREATITIS. (Eng.) Waterworth, M. W.; Barbezat, G. O.; Vinik, A. I.; Bank, S.; Child, P. (Groote Schuur Hosp., Cape Town, South Africa).

Serial serum immunoreactive glucagon determinations were carried out in 15 patients with acute pancreatitis. Six patients who subsequently received either a 1-mg i.v. bolus injection of glucagon or an infusion (15 μg/kg/hr for 6 hr followed by 10 μg/kg/hr for 18 hr) of glucagon had a basal mean blood glucagon level of 500 ± 132 pgEq/ml; the nine remaining patients who served as controls and received no glucagon had a mean basal level of 369 ± 126 pgEq/ml; these levels are approximately 4-5 times higher than normal. The six patients who received glucagon had fivefold increases of circulating immunoreactive glucagon over the basal level. These levels rapidly returned to basal levels after the glucagon infusions had been stopped. Blood glucose levels were significantly higher in patients receiving glucagon than those receiving a placebo. The results demonstrate that most patients with acute pancreatitis have raised blood levels of immunoreactive glucagon.

4988 IDIOPATHIC "JUVENILE" CHRONIC PANCREATITIS. CORRELATION BETWEEN IDIOPATHIC AND ALCOHOL-INDUCED CHRONIC PANCREATITIS. (Ger.) Ammann, R. (Departement fur Innere Medizin, Universitat Kantonsspital, Ramistr. 100, CH-8091 Zurich, Switzerland). *Dtsch. Med. Wochenschr.* 101(49):1789-1794; 1976.

The clinical picture, function, course, and prognosis of 13 cases of idiopathic juvenile chronic pancreatitis seen in 192 cases of chronic pancreatitis are discussed. A genetic disturbance is assumed to be the cause of the disease. Fifty-one of the chronic pancreatitis patients had idiopathic chronic pancreatitis. Idiopathic juvenile chronic pancreatitis can be distinguished from senile chronic pancreatitis by the lower mean age at onset of disease (25.6 yr), predominance of male patients (12/13 patients), typical pancreatitis recurrences (13/13), and frequency of pancreatic calcifications (10/13). The course of the disease appears to be benign, but of long duration.

4989 CHRONIC PANCREATITIS: A CAUSE OF CHOLESTASIS. (Eng.) Scott, J.; Summerfield, J. A.; Elias, E.; Dick, R.; Sherlock, S. (Royal Free Hosp., London, England). *Gut* 18(3):196-201; 1977.

The morphology of the bile ducts was studied using endoscopic retrograde cholangiopancreatography (ERCP), or percutaneous or i.v. cholangiography in 38 patients with nongallstone chronic pancreatitis. Stenosis of the intrapancreatic portion of the distal common bile duct was demonstrated in 11 patients. Ten of the 11 developed transient cholestasis during exacerbations of their chronic pancreatitis. In six, cholestasis eventually persisted requiring surgical relief. Secondary biliary cirrhosis was present in one patient. No evidence of pancreatic carcinoma was found in the patients explored surgically. Ten patients are alive more than 1 yr after diagnosis. Chronic pancreatitis was of alcoholic etiology in 10 patients with biliary stenosis. Cholestasis and biliary stricture are common but poorly recognized complications of nongallstone chronic pancreatitis, especially when pancreatitis is severe and due to alcohol.

4990 WIRSUNG's DUCT OF THE NORMAL PANCREAS AND CHRONIC PANCREATITIS. A STUDY BY SCANNING AND TRANSMISSION ELECTRON MICROSCOPY. (Ger.) Lederer, P.; Stolte, M.; Tulusan, H. (Pathologisches Institut, Universitat Erlangen-Nurnberg, Krankenhausstrasse 8-10, D-8520 Erlangen, W. Germany). *Virchows Arch.* [*Pathol. Anat.*] 372(2):109-121; 1976.

Ninety-six pancreatic duct sections from 39 patients with chronic pancreatitis, 5 patients with retention or concurrent pancreatitis due to carcinoma of the head of pancreas or of the ampulla of Vater, and 6 subjects with a normal pancreas were examined by scanning and transmission electron microscopy. Unlike the normal pancreas, the pancreatic duct in pancreatitis showed alterations in caliber due to tapering or roundish vaults and wrinkles and an undulating surface. The surface of the normal duct consisted of a homogeneous layer of microvilli, but that of the diseased duct showed flattening of the epithelium with loss of microvilli, epithelial defects of varying size, and alternation of elevated and hyperplastic epithelium with flattened epithelium. The typical morphological picture of chronic pancreatitis is the result of a combination of a dilated duct, an irregular caliber due to tapering, and a flattened epithelium with loss of microvilli. The combination of an irregular caliber and an elevated or hyperplastic epithelium is indicative of a still-active inflammatory process.

4991 ORAL CHOLECYSTOGRAPHY AFTER ALCOHOLIC PANCREATITIS. (Eng.) Roller, R. J.; Mallory, A.; Caruthers, S. B., Jr.; Schaefer, J. W. (Denver General Hosp., 8th at Cherokee, Denver, CO 80204). *Gastroenterology* 73(2):218-220; 1977.

Retrospective and prospective studies were carried out to evaluate the efficacy of p.o. cholecystography (OCG) performed before hospital discharge on alcoholic patients with acute pancreatitis. In the retrospective study, OCG adequately opacified the gallbladder in 21 of 26 patients. Of the five patients with inadequate opacification, one was jaundiced at the time of OCG; the other four had OCG before resumption of solid diet. In the prospective study, OCG done in nonjaundiced patients shortly after resumption of food yielded adequate opacification in 19 of 21 patients without gallstones. OCG performed after resumption of a solid diet and before hospital discharge is usuall successful in opacifying the gallbladder in nonjaundiced alcoholic patients with acute pancreatiti not caused by gallstones.

4992 PREVENTION, DIAGNOSIS, AND TREATMENT OF PANCREATIC ABSCESS. (Eng.) Ranson, J. C.; Spencer, F. C. (New York Medical Center, 560 First Ave., New York, NY 10016). *Surgery* 82(1):99 106; 1977.

Factors influencing the genesis of major peripancreatic infection (MPI) were analyzed in 330 patients with pancreatitis. MPI developed in 28. Management of MPI was reviewed in 35 patients, including 7 admitted with MPI. MPI was common in postoperative pancreatitis (39%), compared with alcoholic (6.6%), biliary (3.6%), or other causes (15%). "Severity" of pancreatitis was estimated b 11 early prognostic signs, which were reported previously. With fewer than three signs, MPI develop in 2.7%, with three to five signs, 32%; with more than five signs, 50%. Treatment of pancreatitis also influenced MPI. Early laparotomy increased M incidence from 1.6% to 23% in mild pancreatitis an from 24% to 67% in severe pancreatitis. Early p.o feeding also appeared to predispose to MPI. Prolonged nasogastric suction and avoidance of early operation reduced MPI incidence from 16% in the fi 100 patients to 5% in the next 230 patients. Outcome of MPI reflected severity of underlying pancreatitis. Mortality with fewer than three signs was 14%; with three to five signs, 65%; with more than six signs, 100%. Mortality was only 26% in 1 patients treated with radical sump drainage of the entire peripancreatic retroperitoneum, compared t 75% of 16 patients treated with conventional local drainage. MPI is related to the etiology and severity of pancreatitis as quantified by early signs.

rly laparotomy for pancreatitis increases MPI. eatment of MPI with wide sump drainage appears to e more effective than local drainage.

LIVER AND BILIARY TRACT

03 THE INFLUENCE OF PREDNISOLONE ON HEPATIC FUNCTION IN NORMAL SUBJECTS: EFFECTS ON LACTOSE ELIMINATION CAPACITY, SULFOBROMOPHTHALEIN ANSPORT MAXIMUM AND STORAGE CAPACITY, AND D-GLURIC ACID OUTPUT. (Eng.) Weiersmuller, A.; Colbo, J. P.; Bircher, J. (Dept. Clinical Pharmacology, iv. Berne, Murtenstrasse 35, CH-3010 Berne, Switrland). *Am. J. Dig. Dis.* 22(5):424-428; 1977.

ver function was assessed in nine volunteers fore and after administration of 20 mg prednisone, p.o., for 4 days, to investigate the pharmalogical effects of corticosteroids on liver function tests. Significant decreases in plasma cortisol (mean control level, 17.9 ± 2.4 μg/100 ml; during prednisolone treatment, 1.4 ± 0.9 μg/100 ml) and conjugated bilirubin levels (-40% during treatment) were observed, but the galactose elimination capacity, the BSP tests, and the urinary D-glucaric acid output remained unchanged. No pharmacological effect of this corticosteroid hormone could be detected.

5004 INCREASED LITHOGENICITY OF BILE ON FASTING IN NORMAL SUBJECTS. (Eng.) Williams, C.

N.; Morse, J. W. I.; MacDonald, I. A.; Kotoor, R.; Riding, M. D. (Gastrointestinal Res. Lab., 5849 University Ave., Halifax, Nova Scotia, Canada B3H 4H7). *Am. J. Dig. Dis.* 22(3):189-194; 1977.

The effect of different periods of overnight fasting on bile lithogenicity was studied in 19 normal men and 22 normal women. The molar percentages of bile acid, phospholipid, and cholesterol, determined after random overnight fasts of 9, 12, and 16 hr, were plotted on triangular coordinates. The molar percentage of cholesterol increased in both men and women. Analysis using criteria for cholesterol saturation revealed that 4.50% of normal women were lithogenic at 9.1 hr and 54.5% at 16.5 hr ($p < 0.005$). A similar trend in men was not significant. The mean values for both sexes were lithogenic at 16 hr only. Lithogenic bile was present in four men and one woman at 9 hr fasting and became more lithogenic with longer fasting. Analysis using the criteria of Hegardt and Dam revealed an increased proportion of both sexes moving into the metastable-labile and supersaturated zones on fasting, again with significant changes for women ($p < 0.01$). The duration of fasting is important in interpreting the presence of lithogenic bile; although more pronounced in women, both sexes showed increased cholesterol saturation in bile with fasting.

5005 ALPHA-1-ANTITRYPSIN BODIES IN THE LIVER.

(Eng.) Blenkinsopp, W. K.; Haffenden, G. P. (St. Mary's Hosp., London W2, England). *J. Clin. Pathol.* 30(2):132-137; 1977.

The frequency of alpha-1-antitrypsin cytoplasmic bodies in hepatocytes, thought to indicate the possession of the Z allele for alpha-1-antitrypsin deficiency, was studied in liver necropsy specimens of 64 patients with cirrhosis, 9 with hepatic fibrosis, 15 with hepatocellular carcinoma, 76 with severe panacinar emphysema, and 110 controls. PAS staining, immunofluorescence, or immunoperoxidase methods revealed these bodies in the tissues of 4 controls, 10 patients with cirrhosis ($0.01>p>0.005$), 4 patients with hepatic fibrosis ($p<0.001$), 4 patients with hepatocellular carcinoma ($p<0.001$), and 6 patients with emphysema ($0.30>p>0.20$). Heterozygous (PiMZ) alpha-1-antitrypsin deficiency may be associated with an increased incidence of cirrhosis, hepatic fibrosis, and hepatocellular carcinoma.

5006 COMPARATIVE STUDY OF THE SERUM LEVELS OF NONSPECIFIC CROSS-REACTING ANTIGEN AND CARCINOEMBRYONIC ANTIGEN (CEA): A CLINICAL ASSESSMENT.

(Fre.) von Kleist, S.; Troupel, S.; King, M.; Burtin, P. (Laboratoire d'Immunochimie, Institut de Recherches Scientifiques sur le Cancer, 7, rue Guy Mocquet, B.P. No. 8, 94800 Villejuif, France). *Bull. Cancer (Paris)* 63(4):627-632; 1976.

Serum levels of nonspecific cross-reacting antigen (NCA) and carcinoembryonic antigen (CEA) were measured radioimmunologically using a double-antibody technique in blood donors (controls) and in patients with nonmalignant and malignant diseases. The CEA and NCA levels were comparable in
controls, and NCA levels were slightly elevated in
two of three sera of the cancer patients, ranging
from 150 to 260 ng/ml. However, NCA was highly ele
vated in patients with pulmonary diseases, exceedi
those levels found in lung cancer patients. A
raised NCA level was rare in patients with liver
diseases, and it was only moderately elevated
in intestinal benign or malignant diseases.
NCA levels varied less than those for CEA in colic
cancer patients, and they stabilized between a
mean value of 130 and 150 ng/ml. In benign diseas
the NCA level was significantly higher in men than
in women. No sexual difference was observed in
the cancer patients.

5007 THE DETECTION OF 3β-HYDROXY-5-CHOLENOIC ACID IN HUMAN AMNIOTIC FLUID. (Ger.)

Paumgartner, G.; Deleze, G.; Karlaganis, G.; Giger
W.; Reinhard, M.; Sidiropoulos, D. (Institut fur
Klinische Pharmakologie, Universitat Bern, Murten-
strasse 35, CH-3010 Bern, Switzerland). *Schweiz.
Med. Wochenschr.* 107(15):529-531; 1977.

Studies of amniotic fluid specimens from 18 pregna
women without liver diseases in whom amniocentesis
was indicated because of risk pregnancies suggest
a fetal pathway of bile acid synthesis leading to
the formation of 3β-hydroxy-5-cholenoic acid (3H5)
Bile acids were isolated by gas chromatography.
total concentration of bile acid in amniotic flui
taken between the 28th and 42nd day of gestation
ranged from 0.9 to 2.4 μM. In addition to cholic
and chenodeoxycholic acid, 3H5 was also found in
all specimens. These bile acids are not found in
the serum of healthy subjects. Of the total concentration of bile acids, 33% consisted of cholic
acid, 21% chenodeoxycholic acid, and 34% 3H5. De-
oxycholic acid was only detected in 13 women and
lithocholic acid in 9 pregnant women. The presen
of a considerable amount of 3H5 in amniotic fluid
lends credence to the hypothesis that a fetal pat
way of bile acid synthesis exists that is initiat
by the oxidation of the cholesterol side chain.

5008 ASCORBIC ACID DEFICIENCY IN LIVER DISEA

(Eng.) Beattie, A. D.; Sherlock, S.
(Royal Free Hosp., London, England). *Gut* 17(8):
571-575; 1976.

Since alcoholism and hepatic siderosis are closel
related to liver disease, the prevalence of vitam
C deficiency was investigated in 138 patients wit
liver disease and 28 normal controls. The patien
included 37 with alcoholic liver disease, 25 with
primary biliary cirrhosis, 12 with acute hepatiti
19 with chronic active hepatitis, 13 with cryptogenic cirrhosis, 13 with extrahepatic cholestasis
6 with extrahepatic portal hypertension, 4 with
Gilbert's disease, 3 with Wilson's disease, 3 wit
drug-induced cholestasis, 1 with Budd-Chiari syndrome, 1 with carcinoid syndrome, and 1 with cong
ital hepatic fibrosis. The mean leukocyte ascor
acid (LAA) level was significantly reduced in the
patients with alcoholic liver disease (124.3 ± 7.

M/10^8 WBC, $p<0.01$) and primary biliary cirrhosis
130.0 ± 10.2 nM/10^8 WBC, $p<0.05$) in comparison with
ontrols (161.8 ± 6.8 nM/10^8 WBC). In the primary
iliary cirrhosis patients, cholestyramine therapy
9 patients) was associated with significantly lower
evels of the vitamin (106.2 ± 11.4 nM/10^8 WBC,
<0.05). Liver ascorbic acid measured in biopsies
n 20 patients was significantly correlated with
AA ($r=0.807$, $p<0.001$). No significant correlation
as found between LAA and hematological indices,
onventional liver function tests, or cholesterol
evels in any group of patients. Patients with
AA levels below 100 nM/10^8 WBC had significantly
igher antipyrine half-lives (mean=28.3 hr) than
atients with LAA levels above this level (mean=18.6
r, $p<0.05$). Delayed drug metabolism related to
ow LAA should be considered when drugs metabolized
y the liver are prescribed for patients with alco-
olic liver disease or primary biliary cirrhosis.

009 LABORATORY DIAGNOSIS OF LIVER AND BILE
DUCT DISEASES. (Ger.) Peters, J. E.;
eef, L. (Institut fur Klinische Chemie und Labora-
oriums-diagnostik, Bezirkskrankenhaus Halle, Halle,
. Germany). *Z. Gesamte Inn. Med.* 32(2):29-32; 1977.

complex laboratory diagnosis of hepatobiliary
iseases is proposed on the basis of mathematical
nalyses of data obtained from 1,202 patients with
epatobiliary diseases, 73 patients with other di-
eases, and 45 clinically healthy subjects. Nearly
4% of all patients with hepatobiliary diseases can
e recognized by a preliminary diagnostic program
omprising glutamic-pyruvic transaminase, alanine
minopeptidase, and hepatitis B antigen determina-
ions and relevant clinical findings (palpation,
aundice, and hepatic skin signs). In a further,
ondiscriminatory approach, glutamic-pyruvic trans-
minase, glutamic-oxalacetic transaminase, leucine
minopeptidase, alkaline phosphatase, alanine amino-
eptidase, cholesterol, bilirubin, β-glucuronidase,
nd thymol tests should be used to eliminate false-
ositive cases and to establish the class of hepato-
iliary disease. A BSP test is justified for the
ollow-up of cirrhotic patients and patients in
hom the preliminary diagnostic and anamnestic data
o not permit plausible interpretation.

010 LIVER ANGIOMA. (Fre.) Gruner, M.; Jab-
lonski, J. P. (No affiliation given).
n. *Chir. Infant.* 17(5/6):408-419; 1976.

he symptoms and treatment of 39 children with liver
ngiomas (LA) are described. The diagnosis was
ade histologically in 31 patients, on operation
n 4, and by arteriography in 4. Two types of LA
ere observed: solitary (23) and multinodular (13).
he latter was more frequent among females and,
n most cases, was manifested by a marked increase
n the size of the abdomen. Cardiac involvement
nd cutaneous or visceral angiomas were evident in
ix patients. Six patients without cardiac involve-
ent did not have cutaneous angiomas, but their
iver sizes were greater than the former group.
adiological tests revealed calcifications in one
patient and vascular calcifications in two. Marked anemia was observed in 8/10 patients, and 2 of these had elevated transaminase levels. Radiotherapy was given to 10 children: 4/6 with LA plus cardiac insufficiency were cured but 2 died (1 at the start of and 1 after treatment). Three of six patients without cardiac involvement who received radiotherapy were cured, whereas two died either at the start of or after treatment. Corticoid therapy was ineffective in two children. Surgery was given to 10/13 patients. Seven were cured (all had been irradiated) and five died. Of the 23 solitary LA, 13 were on the left side of the liver, 8 on the right, and 3 were in the center. Peritumoral adherences were very marked in three patients. Upon surgical exploration, the fragility of the tumor resulted in pseudocapsule rupture with uncontrollable hemorrhaging. Treatment consisted of surgery in 17 patients and radiotherapy in 4. Six of the former group died of surgical complications. Three of the four irradiated patients were cured and one died. Surgery is not the ideal treatment for LA and should only be used for massive tumors. Radiotherapy is the preferred treatment.

5011 ECHOTOMOGRAPHY OF LIVER TUMORS IN CHILDREN. (Fre.) Gauthier, N.; Bonnin, A. (No affiliation given). *Ann. Chir. Infant.* 17(5/6):372-379; 1976.

Echotomography was used to evaluate liver tumors in 12 children with benign tumors (1 hamartoma), malignant tumors (6 hepatoblastomas), metastases (3), and a hydatid cyst (2). Liquid and solid tumors were distinguished. The former included the hamartomas and hydatid cysts, and they evoked a weak echo. The solid tumors (i.e., the hepatoblastomas) and, to a lesser extent, the metastases evoked a stronger echo.

5012 BIOLOGICAL CONTRIBUTION TO THE DIAGNOSIS OF PRIMARY LIVER TUMOR. (Fre.) Buffe, D.; Rimbaut, C. (Laboratoire d'Immunochimie, Institut de Recherches sur le Cancer, Villejuif, France). *Ann. Chir. Infant.* 17(5/6):379-385; 1976.

The usefulness of the α-fetoprotein (AFP) test and other biological tests in the detection of malignancies is presented. The AFP test was positive in 43/49 sera of children with confirmed hepatomas or hepatoblastomas, as determined by immunodiffusion. Two of the negative sera were positive when tested by radioimmunodiffusion. In a series of 494 other malignancies with or without hepatic metastases, the test was positive in 87% of the patients with malignant teratomas and in 91% of those with hepatomas or hepatoblastomas. A positive AFP test was also observed in 25 patients with hepatitis, 5 with tyrosinosis, and 3 with atresia of the intrahepatic bile duct. The test was always negative in benign hepatic tumors. The AFP level varied from 1 mg/ml in acute hepatitis to 600 ng/ml in hepatomas. Further, α_2H globulins were detected in 80% of tumor patients, especially those with liver cancer. The presence of carcinoembryonic antigen has been associated with tumors of the digestive tract. Other biological compounds tested to indicate the presence of malignancies include coagulation factors, alkaline phosphatase, aldolase, and transaminases.

5013 RADIOLOGICAL ASPECTS OF PRIMARY LIVER TUMOR IN CHILDREN. (Fre.) Hassan, M.

(Service de radiologie, Hopital des Enfants Malades, 149, rue de Sevres, 75015 Paris, France). *Ann. Chir. Infant.* 17(5/6):357-382; 1976.

Arteriographic studies of primary liver tumor (LT) were performed in 43 children. All patients were explored by global aortography (method of Seldinger), sometimes complemented by a selective injection. There were 29 malignant tumors (MT) and 14 benign tumors (BT). Arteriography was positive for LT in 40/43 patients and inconclusive in 1 case each of hamartoma, multinodular capillary angioma, and abnormal vascularization. The most characteristic vascular symptomatology of the malignant tumors included the penetration of new vessels into the tumor, early venous intratumor opacification, and an inhomogenous appearance of the parenchymal myography. The symptoms of benign tumors were much less consistent, and they were classified as cystic avascular, hypervascular, mixed, and silent forms. The first two were recognized easily. Mixed forms were usually large, with the vascularization classically considered malignant. All four forms showed common features: the hypervascularization was distal and peripheral and was made up of small, sometimes dysplasic vessels. The hypervascularization did not seem to penetrate the tumor, but remained at its periphery. Benign tumors had a network of large, dysplasic arteries, whereas malignant tumors had a normal number of arteries.

5014 CLINICAL ASPECTS OF LIVER TUMORS. LOCALIZATION OF LIVER TUMORS. (Fre.) Prevot, J.; Duval, J.

(No affiliation given). *Ann. Chir. Infant.* 17(5/6):348-358; 1976.

The problems of correctly diagnosing liver tumors in children are surveyed briefly. Tumefactions of nonhepatic origin may mimic liver tumors. A 1-yr-old child presented with a large tumor of the median epigastric region that simulated a renal or liver tumor. However, barium transit revealed a tumor of pancreatic origin that turned out to be a giant primary cyst of the head of the pancreas. Hepatic tests and a myelogram were normal in a 6-yr-old boy who was hospitalized for a tumor in the right hypochondrium with colic compression and microcalcifications. At laparotomy, a large extrahepatic retroperitoneal tumor was excised. In a 2-yr-old boy, arteriography revealed a retroperitoneal embryonic sarcoma. Hepatic scintigraphy, however, was normal. One 6-yr-old girl presented with a mass in the left flank without specific humoral retention, indicative of a kidney tumor, although i.v. urography was normal. Surgery revealed a hemangioendothelioma. Other cases observed include liver tumors of ectopic localization, hepatic hamartomas simulating a mesentery cyst, and a calcified hemangioma with digestiv symptomatology evoking the diagnosis of digestive duplication or sympathoblastoma.

5015 PRIMARY LIVER TUMORS IN CHILDREN. PATHO-ANATOMICAL STUDY OF 100 CASES. (Fre.)

Gubler, J. P.; Gerard-Marchant, R.; Nezeloff, C. (Hopital Saint-Vincent-de-Paul, 74, ave. Denfert Rochereau, 75674 Paris Cedex 14, France). *Ann. Chir. Infant.* 17(5/6):330-347; 1976.

Pathoanatomical studies of primary liver tumors in children, including 35 benign tumors and 58 malignant tumors, were made using the histopathological records. Benign tumors could generally be classified as hamartomas (HA) because whatever the degree of differentiation or macroscopic appearanc they always possessed several tissue components. The studies revealed that benign tumors were comprised of solitary angiomas (8), multicomponent HA (13), fibroblastic HA (7), angiomyoxoid HA (4), and a lymphangioma (1). The malignant tumors either sarcomatous or blastomatous, had a varied morphology. In some cases, only part of the orga was invaded. Hepatoblastomas (HB) were observed in 46 cases, and in 32, blastomatous tissue was present. The histopathology of the HB varied. Many contained erythropoietic cells or angioform mesenchymatous islets. Biopsy samples from HB patients revealed were inconclusive. Hepatocarcin mas, which were seen in eight patients, were characterized by differentiated trabecular or cana trabecular proliferation.

5016 EARLY DIAGNOSIS OF CARCINOMA OF THE HEPATIC DUCT. (Ger.) Cueni-Heer, E.; Cuer

B.; Schmid, M. (Medizinische Klinik, Stadtspital Waid Tiechestr. 99, CH-8037 Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 107(15):534-537; 1977.

The clinical symptoms and course of carcinoma of the hepatic duct in eight patients are presented. A retrospective study of the eight patients showe that all presented with upper abdominal pain with an anicteric period of 2-23 months prior to diagnosis. Six patients had short, intermittent episodes of diarrhea, two had weight loss, and one had pruritus during the anicteric period. A slightly enlarged liver was seen twice, six had occult blood in the stool, and only one patient h a persistently elevated alkaline phosphatase leve in the anicteric stage. However, in the icteric stage, all patients had enlarged livers, pruritus nausea, and rapid deterioration in condition. Li chemistry was inconsistent. Liver biopsies in th anicteric stage showed cells with feathered degeneration of the cytoplasm (pseudoxanthoma cells), indicative of longstanding cholestasis. These ce were also found in three biopsies during icterus. Upon diagnosis, the carcinoma had infiltrated the hepatic parenchyma in all patients, and in seven stances, it had encircled the hilar vessel struct Two patients had a hepaticojejunostomy, and a bil duct prothesis was inserted in five others; one patient had no surgery. All patients died 2-32 m after diagnosis of gallbladder complications, hemato-bilia, or cachexia.

5017 PROBLEMS OF THE DIAGNOSIS OF LIVER TUMORS IN HEPATOMEGALY. (Fre.) Dommergues, J. P. (Service d'Hepatologie Infantile, Hopital Parrot, Bicetre, 94, Le Kremlin Bicetre, France). *Ann. Chir. Infant.* 17(5/6):353-356; 1976.

Problems in diagnosing pediatric hepatic hypertrophy (HH) presumed to be of tumoral origin are discussed. An isolated nodular mass should be distinguished by its palpatory features and differentiated from the neighboring hepatic parenchyma. If HH has affected the entire lobe, certain diagnostic traps have to be avoided, and the following should be taken into consideration: the frequent asymmetry of cirrhosis and the existence of congenital atrophy of the left lobe with rare, compensating physiological hypertrophy of the right lobe. If the liver is enlarged and more or less irregular and nodular in shape, cirrhosis, glycogenosis, and secondary hepatic tumors should be excluded. In infants, the discovery of a very large abdominal mass can complicate the diagnosis. Should cardiac insufficiency also be present, hepatic or multinodular hemangiomatous angioma may be diagnosed. Hematological abnormalities such as anemia, hyperthrombocytopenia, and thrombopenia should also be considered. Hepatic function tests are only slightly disturbed in primary liver tumors. In some instances, measurement of urinary catecholamines has verified the presence of sympathoblastoma, whereas a positive α-fetoprotein test has been indicative of hepatoblastomas in children <2 yr of age and in certain cases of metabolic cirrhosis, which may include tyrosinosis and Wilson's disease.

5018 POSSIBLE MANIFESTATIONS OF MALIGNANT TUMORS OF THE LIVER. (Fre.) Juskiewenski, . (No affiliation given). *Ann. Chir. Infant.* 17(5/6):430-432; 1976.

The possible manifestations of malignant tumors of the liver (LT) are reviewed. The association of LT with certain congenital malformations of the urogenital, digestive, or circulatory systems is not valid statistically. Eight cases of congenital hemihypertrophy have been reported, and it has also been observed in Wilms' tumor and adrenal tumors. The association of LT with delayed puberty in a young adult has been documented by only two authors, whereas association of LT with a virilization syndrome has been reported frequently. The virilization syndrome is characterized by acceleration of bony maturation and a marked increase of urinary gonadotropin levels. This syndrome has not been observed in girls.

5019 PARTICULAR ASPECTS OF LIVER TUMORS. SECONDARY LIVER TUMORS. (Fre.) Schweisguth, O.; Zucker, J. M. (No affiliation given). *Ann. Chir. Infant.* 17(5/6):390-398; 1976.

The specific aspects and therapeutic results of neuroblastoma with hepatic metastases in 37 children are reported. Hepatomegaly occurred in the first months of life, nearly always before 6 months. The liver was usually solid; no icterus was present. The urinary catecholamine level was highly elevated in all of the children. I.v. urography revealed displacement of the kidney by a thoracic tumor in two children and by a cervical tumor in one. Treatment usually consisted of radiotherapy (1,000 rads) to the liver over 10-15 days, followed by alternating chemotherapy with vincristine (1.5 mg/m^2 i.v.) every 2 weeks and cyclophosphamide (300 mg/m^2 i.v.) during the intermediate weeks. This was continued until the urinary catecholamine levels returned to normal. Five children died <10 days after hospitalization, but 11 survived >5 yr, 8 >2 yr, and 4, 1-4 yr. Seven of the patients died after 2 months to 6 yr of tumor recurrence, most often of the ganglia or skeleton and less frequently of the liver.

5020 CLINICAL ASPECTS OF INTRAHEPATIC BILE DUCT CARCINOMA INCLUDING HILAR CARCINOMA: A STUDY OF 57 AUTOPSY-PROVEN CASES. (Eng.) Okuda, K.; Kubo, Y.; Okazaki, N.; Arishima, T.; Hashimoto, M.; Jinnouchi, S.; *et al.* (Chiba Univ. Hosp., Chiba, Japan). *Cancer* 39(1):232-246; 1977.

The clinical features of 57 autopsied cases of intrahepatic bile duct carcinoma, including 28 cases of the peripheral type (cholangiocarcinoma) and 29 cases of the hilar type, were compared with those previously reported for hepatocellular carcinoma. Among the 57 cases, the male/female ratio was 1.7:1, whereas that of hepatocellular carcinoma was 7.2:1. The average age of the patients was 62.2 yr, almost 10 yr older than that for hepatocellular carcinoma (53.8 yr). Jaundice was more frequently the initial presenting symptom in bile duct carcinoma (26.3%) than in hepatocellular carcinoma (0.8%). Ascites were present in 15.8% and 49.3% of patients with intrahepatic bile duct carcinoma and hepatocellular carcinoma, resp. Hepatomegaly occurred in only 50.8% of patients with bile duct carcinoma, whereas it was more frequent in hepatocellular carcinoma. Splenomegaly was absent in all cases of bile duct carcinoma, whereas it occurred in 16.4% of patients with hepatocellular carcinoma. Signs of portal hypertension were absent or minimal in the patients with intrahepatic bile duct carcinoma, and extrahepatic metastases were less frequent than in hepatocellular carcinoma. The clinical course of the hilar type of intrahepatic bile duct carcinoma resembled extrahepatic bile duct carcinoma; that of the peripheral type was between the latter and hepatocellular carcinoma. The major diagnostic procedures employed included percutaneous transhepatic cholangiography, endoscopic retrograde cholangiography, liver scanning, celiac angiography, laparoscopy, liver biopsy, exploratory laparotomy, and blood chemistry. The overall rate of histologically correct diagnosis was 31.5%. The diagnosis became more accurate in cases after 1970, particularly in the hilar type, due to the development of direct cholangiographic techniques and alpha-fetoprotein determination. Two illustrative cases are presented, including one patient with a hilar carcinoma who survived for over 2 yr after transhepatic biliary drainage.

5021 BIOPSY FINDINGS OF LIVER PARENCHYMA IN THE PRESENCE OF METASTASIS.

(Ger.) Dirschmid, K. (Institut fur Pathologie, Carinagasse 49, A-6807, Feldkirch, Austria). *Zentralbl. Allg. Pathol.* 121(3):225-228; 1977.

The morphological changes seen in 107 liver biopsies with metastatic tumor infiltration are presented. Nonspecific reactive hepatitis was observed in almost 50% of the specimens, whereas passive hyperemia (9 focal, 3 with necroses, 2 atrophy) was seen in 30%. Other liver findings included necroses (35 times), compression (23), intrasinusoidal granulocytic concentration (16), pure tumor tissue (12), scars (11), little tumor tissue (7), cholestasis (6), myeloid metaplasia (1), concurrent secondary biliary cirrhosis (1), stationary cirrhosis (1), and alcoholic fatty liver (1). The case of myeloid metaplasia was attributed to widespread metastases of the skeletal system. The frequent nonspecific reactive hepatitis can be attributed to the tumor metabolism and immunological reaction to the tumor tissue, which was most intense in the proximity of the tumor. Granulocytic intrasinusoidal accumulations can be considered as leukotactic reactions to tumor necrosis. Overall, the detection of metastases was unexpected in 14% of the biopsies. The results prove the usefulness of liver biopsies in detecting unexpected liver metastases.

5022 IMMUNOPATHOLIGICAL ASPECTS OF LIVER CIRRHOSIS.

(Ger.) Meyer zum Buschenfelde, K. H. (II. Medizinische Klinik, Klinikum der Johannes-Gutenberg-Universitat, Langenbeckstrasse 1, D-65 Mainz, W. Germany). *Z. Gesamte Inn. Med.* 32(1):10-16; 1977.

The immunopathological aspects of hepatobiliary diseases are reviewed. Acute viral hepatitis B was found to progress to chronic active or persisting hepatitis or liver cirrhosis in about 4-11% of all cases, especially if hepatitis B surface antigen (HBsAg) persisted for >13 weeks. With the immune system being unable to reject the virus and virus-infected cells, the infected cells underwent transformation, followed by the appearance of virus antigens on the cell surface and autoimmune reactions. Sudden cure was observed in some cases of chronic active hepatitis with long-term HBsAg after HBsAg and hepatitis B core antigen were eliminated from the serum and tissue upon transition of the disease into liver cirrhosis. Excessive hypergammaglobulinemia, persistently high IgG levels, antinuclear antibodies, cellular immunity to membrane antigens, antimembrane autoantibodies, and histocompatibility antigen 8 are found in autoimmune chronic active hepatitis. Circulating antinuclear antibodies in patients with drug-induced chronic hepatitis and liver cirrhosis indicate the involvement of immunological mechanisms. The presence of antimitochondrial antibodies and associated autoimmune diseases (Sjogren's syndrome, chronic polyarthritis, rheumatoid arthritis, and autoimmune thyroiditis) in primary biliary cirrhosis indicate
that it is a special form of immunological liver disease. Unlike other localized and generalized autoimmunopathies, it is not influenced by immunosuppressive therapy.

5023 AMINOPYRINE METABOLISM IN THE PRESENCE
HYPERBILIRUBINEMIA DUE TO CHOLESTASIS O
HEPATOCELLULAR DISEASE: COMBINED USE OF LABORATOR
TESTS TO STUDY DISEASE-INDUCED ALTERATIONS IN DRUG
DISPOSITION.

(Eng.) Hepner, G. W.; Vesell, E. S.
(Univ. California at Los Angeles/Harbor General Hosp., Torrance, CA 90509). *Clin. Pharmacol. Ther*
21(5):620-626; 1977.

The aminopyrine breath test (ABT) was performed in
patients with hyperbilirubinemia to determine why cholestasis has variable effects on hepat
aminopyrine metabolism. Hyperbilirubinemia (total
serum bilirubin >1.2 mg/100 ml) in these patients
was due to hepatocellular disease (77 cases) or ch
estasis (40 cases). The ABT, defined as the percentage of the administered dose of ^{14}C excreted i
breath for 2 hr after [^{14}C]aminopyrine administration, was 6.2 ± 0.8% in 107 control patients with
normal total serum bilirubin. The ABT was severel
abnormal (<3.1%) in 54/77 hyperbilirubinemic patients with hepatocellular disease and normal (>4.5%) in only 5 of these patients. In contrast, the ABT was severely abnormal in only 1 of
40 cases of cholestasis with hyperbilirubinemia a
normal in 70% of these patients. Thus, aminopyri
metabolism is normal in most cases of hyperbiliru
inemia due to cholestasis and is only rarely seve
ly abnormal in these patients. Severe abnormalit
in aminopyrine metabolism occurs in the majority
patients with hyperbilirubinemia due to hepatoce
lar disease. It appears that the ABT may be usef
to distinguish patients with hyperbilirubinemia d
to cholestasis from most patients with hyperbilir
binemia due to hepatocellular disease.

5024 INTRAHEPATIC CHOLESTASIS IN CHILDHOOD.

(Eng.) Heathcote, J.; Deodhar, K. P.;
Scheuer, P. J.; Sherlock, S. (Royal Free Hosp., P
St., London, NW3 2QG, England). *N. Engl. J. Med.*
295(15):801-805; 1976.

The clinical course, histologic features, and pos
ble etiologic factors in 17 children with cholest
in the neonatal period were studied. During a fo
low-up period of 5 months to 22 yr, all had signs
of chronic cholestasis, but only 4 died (2 from n
hepatic causes); the others live remarkably norma
lives. Serial hepatic biopsies in 11 showed a va
iety of initial lesions, which progressed to hypo
plasia of the intrahepatic bile ducts; increasing
evidence of possible viral infection was found i
only 10 cases; a hepatitis, beginning either bef
or after birth, appears to be a likely original
cause. The histologic changes may represent dif
ent stages of one process, starting as cholestas
with or without evidence of hepatitis and progre

sing to obliteration or failure of normal growth of the intrahepatic bile ducts.

5025 METABOLISM OF HYPNOTIC AND SEDATIVE DRUGS IN CHOLESTASIS. (Ger.) Denk, H. (Pathologisches-Anatomisches Institut der Universitat Wien, Spitalgasse, A-1090 Vienna, Austria). *Z. Gastroenterol.* 6(15):373-377; 1977.

The biotransformation of hypnotic and sedative drugs was found to be impaired in cholestatic rats and rabbits. Hexobarbital and pentobarbital sleeping times were significantly prolonged in these ligated animals. In the rat, ligation of the bile duct resulted in a biochemically and morphometrically tangible increase in the rough and smooth endoplasmic reticulum of the liver cells. The endoplasmic reticulum was hypoactive with respect to drug metabolism, a condition partially due to decreased glucose-6-phosphatase activity in the endoplasmic reticulum and decreased cytochrome P-450 content in the microsomes. Tests with microsomes of cholestatic rats showed a mixed competitive-noncompetitive inhibition during aminopyrine degradation that depended on the age of the animal. Drug elimination was also altered in cholestatic patients. The half-life of serum pentobarbital was lengthened in patients with mechanically-induced cholestasis, but the half-life of meprobamate was not changed significantly. Similarly to test animals, the cytochrome P-450 content in the liver homogenates of patients with cholestasis and choledocholithiasis was decreased significantly. *In vitro* studies with liver specimens from these patients also showed a markedly reduced metabolism of hypnotics and sedatives.

5026 HEPATIC ENCEPHALOPATHY AND REYE'S SYNDROME. (Eng.) Partin, J. C. (No affiliation given). *Pediatr. Ann.* 6(5):101-113; 1977.

The clinical and biochemical features of Reye's syndrome (RS) are contrasted with those of hepatic encephalopathy (HE) of fulminant hepatitis. Reye's syndrome is an acute complication of an otherwise trivial childhood viral infection, and most cases of RS masquerade briefly as gastroenteritis. Usually, clear signs of encephalopathy develop within hours of the onset of vomiting in RS, in contrast to HE where the signs of hepatitis usually precede the onset of encephalopathy by days or weeks. Jaundice is absent in RS patients and is usually present on admission in HE patients. The liver size is normal or considerably enlarged in RS and may be impalpable in HE. Fetor hepaticus is absent in RS and is usually present in HE. The liver biopsy of RS is yellow or white and very fatty, as opposed to a green nonfatty specimen in HE. Biochemically, the bilirubin value is less than 3.5 in RS, in contrast to a value of more than 5 in HE. The blood sugar of RS patients may be hypoglycemic and readily correctable; hypoglycemia in HE may be profound and difficult to correct. In both RS and HE, the SGOT and SGPT levels are elevated and variable. Ammonia levels are elevated in RS before treatment and normalize rapidly with treatment; in HE, the ammonia levels are unpredictable. Prothrombin time, which is prolonged in both RS and HE, is easily corrected in RS and may be difficult to correct in HE. Disseminated intravascular coagulopathy (thrombocytopenia) is absent in RS and may be present in HE. The liver lesion in RS is almost always completely reversible in patients treated by exchange transfusion or by glucose infusion. The mortality for hospitalized cases of RS is about 40%, although this has been reduced to 20% by the use of special treatment teams.

5027 THE ROLE OF THE FALSE NEUROTRANSMITTER OCTOPAMINE IN THE HYPOTENSION OF FULMINANT HEPATIC FAILURE. (Eng.) Trewby, P. N.; Chase, R. A.; Davis, M.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5 9RS, England). *Clin. Sci. Mol. Med.* 52(3):305-310; 1977.

The mechanism of unexplained hypotension in fulminant hepatic failure was studied in 23 patients. Serum octopamine, systemic peripheral resistance, the pressor response to tyramine infusions, and the sensitivity of the peripheral vessels to released noradrenalin were assessed. Seventeen patients became hypotensive during hepatic failure, with a systolic blood pressure of less than 80 mm Hg, which was not accounted for by hemorrhage or septicemia. The mean peripheral resistance in the eight hypotensive patients studied (1.93 ± 0.23 kPa min/$1/m^2$) was significantly lower than that in nine patients who were normotensive (2.91 ± 0.29 kPa min/$1/m^2$). Compensatory tachycardia was not observed in the hypotensive patients, and their mean heart rate was significantly slower than that in the normotensive patients (93.7 ± 5.0/min and 108.7 ± 3.3/min, resp., $p<0.02$). Serum octopamine concentrations were raised in both normotensive and hypotensive patients, with a mean value for the entire group of 17.63 ± 0.85 nM, compared with 11.43 ± 1.24 nM in controls ($p<0.001$); the highest concentrations were found in the normotensive patients. The pressor response to tyramine (3, 6, and 9 mg, i.v., 18 patients) did not differ significantly from control subjects or between the normotensive and hypotensive patients. The pressor response to noradrenalin (3, 6, and 9 µg) was not significantly different in the controls, normotensive, and hypotensive patients. Only one patient who developed hypotension recovered conciousness, while five of the six patients remaining normotensive recovered. The results suggest that neither increased serum concentrations of the false neurotransmitter octopamine nor end-organ insensitivity to released noradrenalin are responsible for the hypotension. A more likely explanation is toxic depression of the vasomotor center.

5028 ARTIFICIAL SUPPORT SYSTEMS FOR LIVER FAILURE. (Eng.) Berk, P. D.; Scharschmidt, B. F.; Martin, J. F.; Plotz, P. H. (Building 10, Room 4D52, DDB:NIAMDD, Natl. Inst. Health, Bethesda, MD 20014). *Kidney Int.* 10(Suppl. 7):S233-S238; 1976.

Approaches to the development of an artificial hepatic support system are reviewed. The application of such a device presently appears to be limited to short-term use in potentially reversible acute hepatic failure. The experimental artificial liver devices include hemodialysis, hemoperfusion through sorbents, affinity chromatography, biologically active adsorbents, and hemoperfusion through liver cells in tissue culture. Conventional hemodialysis results in an approximate 50% survival rate. Since the toxins responsible for hepatic coma are among the "middle molecules," which are not efficiently removed by this procedure, the development of hollow fiber artificial kidneys capable of clearing substances with molecular weights up to 5,200 is of potential interest. Hemoperfusion through charcoal effectively removes many middle molecular weight molecules, but does not remove nondialyzable, tightly protein-bound materials, such as bilirubin. Although hemoperfusion through resins has been employed in the treatment of drug overdose, the striking losses of WBC (60-80%) and platelets (60-98%) noted in animal and clinical trials has not encouraged their widespread use in hepatic failure. Affinity chromatography with albumin-agarose gel effectively removes bilirubin, indocyanine green, BSP, certain bile acids, and some albumin-bound drugs from whole blood or plasma *in vitro*. To the extent that tightly albumin-bound substances play a role in hepatic coma, albumin-agarose gel hemoperfusion may be of potential value as a component of a temporary hepatic support system for acute liver failure. Detoxification by extracorporeal circuits containing columns of biologically active materials has been occasionally described with gel-entrapped hepatic microsomes and with solubilized, carrier-bound hepatic enzymes. Hemoperfusion through liver cells in tissue culture has been described, but limitations of both capacity and scale may be obstacles to its clinical application. None of the approaches tested clinically has conclusively proved to be beneficial in fulminant hepatic failure. Further understanding of basic organ physiology and of the pathophysiology of organ failure is necessary.

5029 HEPATIC HAMARTOMA (32 CASES, ANGIOMATOUS AND LYMPHANGIOMATOUS HAMARTOMAS EXCLUDED).

(Fre.) Nihoul-Fekete, C. (No affiliation given). *Ann. Chir. Infant.* 17(5/6):399-423; 1976.

The macroscopic appearance, clinical study, and treatment of 32 children with hepatic hamartomas (HT) are presented. Some HT (15/32) had a cystic appearance and large volume, and 21 were superficial. According to the vascular segmentation, 18 HT were on the right side of the liver, 10 on the left, and 2 were in the center. One case of multiple biliary adenoma and one of multinodular adenoma were also observed. A clinical study showed that of 30 HT (excluding 2 diaphragmatic hernias), 17 originated in the liver and 3 in the spleen. Topography resulted in a false diagnosis in two patients, and technetium scintigraphy did not differentiate an intraparenchymatous lacuna from compression images caused by a neighboring tumor. A biopsy of the 17 solid tumors revealed 8 adenohamartomas, 4 cholangiohamartomas, and 5 composite HT. Three children died before surgery could be undertaken, but 29 underwent surgery. Eight patients underwen a typical hepatic exeresis, seven were cured, and one died of anesthetic complications. All 13 patients whose tumors were excised were cured. Right hepatectomies were performed in five childre with large solid tumors, but two died. Internal drainage with a Y loop was performed in one child months after external drainage (marsupialization) central biliary cyst complicated by a fistula. H cured 8 yr later. Exeresis could not be performe in two children, and they are still alive after 5 and 14 yr. In view of the serious nature of this histologically benign tumor (6/32 died), surgical intervention should be attempted.

5030 GIANT MULTIFOCAL CAVERNOUS HEMANGIOMA O THE LIVER WITH PHLEBOLITHS.

(Ger.) Ho U.; Friedrich, M.; Sorensen, R. (FU Berlin, Klinikum Steglitz, Hindenburgdamm 30, D-1000 Berlin 45, W. Germany). *Radiologe* 17(2):77-82; 1977.

A giant, multifocal, cavernous hemangioma of the liver with phleboliths was diagnosed in a 31-yr-o man. The fluid-filled, space-occupying formation was diagnosed by sonography and liver angiography (selective angiography of the hepatic artery, ret grade angiography of the hepatic vein, and indire angiography of the portal vein via the splenic ar tery and superior mesenteric artery). Retrograde angiography of the hepatic vein is of great diffe ential diagnostic value.

5031 DIAGNOSIS OF HYDATID CYST OF THE LIVER.

(Fre.) Carcassonne, M.; Aubrespy, P. (No affiliation given). *Ann. Chir. Infant.* 17(5 395-398; 1976.

The diagnostic results of 70 hydatid cysts (HC) the liver in 24 girls and 14 boys are presented. Twenty of the patients with HC also had liver tumors. The hydatid cysts were located on the right side of the liver in 25 children, on the left in 9, and bilaterally in 4. With the except of one case, no overall hepatomegaly was noted, a mass of variable hardness was obvious. It occu red singly in 18 patients and multiply in 20. I was the main symptom in all patients and was som times associated with a high body temperature. Ten children, who had no liver tumors, presented with classical symptoms of appendicitis or a tum of the right hypochondrium. Echography was used to localize the large cysts, but, like scintigra it was not capable of detecting smaller ones. Splenoportography, however, accurately defined t appearance, number, localization, and portal con nection of the cysts. Cavography was recommende along with splenoportography to delineate the ve cava and the subhepatic circulation.

5032 TREATMENT OF HYDATID CYST.

(Fre.) Aubrespy, P.; Carcassonne, M. (No affi ation given). *Ann. Chir. Infant.* 17(5/6):470-4 1976.

The treatment of 38 patients with 61 hydatid cysts (HC) by total (31) and subtotal (3) cystectomy, pericystectomy (15), cystoresection (4), and external drainage (8) are reported. During these procedures the following complications developed: intracavitary effusion (3), purulent subdiaphragmatic abscess (1), and secondary echinococcosis (1). Overall, surgery for HC is less burdensome in children than in adults.

5033 FOCAL NODULAR HYPERPLASIA OF THE LIVER. REPORT OF TWO CASES IN ADULTS. (Fre.) Arnaud, J. P.; Weill-Bousson, M.; Adloff, M.; Imler, M. (Service de Chirurgie du Centre medico-chirurgical, 19, rue L. Pasteur, F 67300 Schiltigheim, France). *Arch. Fr. Mal. App. Dig.* 65(5): 397-403; 1976.

The diagnosis and surgical treatment (hepatic resection) of two patients with focal nodular hyperplasia (FNH) of the liver are presented. One patient had only pain in the right lumbar cavity and normal liver function tests. However, arteriography of the celiac trunk revealed tumoral formation of the right liver lobe with malignant hypervascularization, plus an incomplete nephrogram of the right kidney. Surgery revealed a tumor, and a right hepatectomy was performed successfully. Histology demonstrated FNH of the liver. The other patient presented with intense icterus associated with asthenia, anorexia, and elevated transaminase levels. Despite vitamin therapy, the patient developed hepatic encephalopathy with complete coma, disturbed EEG, increased arterial ammonia level, and a breakdown of coagulation factors. The patient became conscious 4 days later following treatment with antibiotics, corticoids, and an injection of human anti-Australian immunoglobulins. The icterus and cytolysis diminished gradually, but this was followed by edematous ascitic decompensation with a new surge of icterus. Biological tests finally became normal, and the general condition improved after corticoid treatment. A subsequent hepatic biopsy revealed the start of posthepatic cirrhosis, liver function tests were abnormal, and arteriography of the celiac trunk and hepatic artery showed a polycyclic lacuna in the right lobe. Surgery revealed five irregular and nodular formations in the hepatic parenchyma. Anatomic-pathological examination of the tissue revealed a thin sheet of hepatocytes encircling the nodules, but no sign of malignancy.

5034 ULTRASTRUCTURAL RESULTS IN LIVER BIOPSIES OF PATIENTS WITH HYPERLIPOPROTEINEMIA. (Ger.) Kemmer, C.; Henefeld, M. (Pathologisches Institut, Medizinische Akademie "Carl Gustav Carus," Fetscherstrasse 74, DDR-8019 Dresden, E. Germany). *Zentralbl. Allg. Pathol.* 121(3):243-253; 1977.

Electron microscopy findings of liver biopsies from 24 patients with types IIa-V endogenous hyperlipoproteinemia (HLP), 7 patients with steatosis hepatitis, and 6 healthy controls are presented. Liver cells of type IIa HLP patients showed marked proliferation of the smooth endoplasmic reticulum and mitochondria with some atypical cell membrane, paracrystalline matrix inclusions, or fibrillar matrix condensation. In addition to the proliferation of smooth membrane, type IIb patients also showed more severe alterations of liver cells, depending on the degree of fatty degeneration. Sporadic giant mitochondria, paracrystalline matrix inclusions, and myelin-type degeneration foci appeared in the mitochondria. Type III specimens showed marked hydration of the cytoplasm of hepatocytes, as well as increased deposits of larger neutral fatty drops. Stronger changes were seen in the Golgi areas, with vacuolization of the membrane parts and accumulation of lipidic substances of various density and structure in the cisternae and larger vesicles. In type IV biopsies, irregular structures of the liver cells predominated, along with marked dilation of the membrane of the endoplasmic reticulum. Polymorphy of the mitochondria was conspicuous, combined with frequent rearrangement of the cristae and myelin-type membrane degeneration. Organelles with dense, partial, fibrillar structured matrixes were pronounced. More severe defects of the liver cell membrane and endothelium were seen in type V HLP. All these patients showed mitochondrial polymorphy, with partial bizarre shaped organelles, atypical cell membrane, and paracrystalline matrix inclusions. The hyperplastic Golgi areas contained vesicles with lipoprotein particles and electron-dense aggregates and myelin-type structures. Patients with type III-V HLP and concomitant diabetes mellitus had glycogen in liver cell nuclei, in addition to more fatty- and glycogen-rich liver cells. A fine structural differentiation between findings in HLP plus steatosis hepatitis and fatty liver without HLP could not be made. No significant liver findings were noted in the controls.

5035 DIAGNOSIS OF CHOLESTATIC JAUNDICE IN INFANTS. DISCRIMINATORY STUDY OF 288 CASES. (Fre.) Eliot, N. (INSERM U-56, Hopital d'Enfants, 78, rue du General-Leclerc, F 94270 Le Kremlin-Bicetre, France). *Biol. Gastroenterol. (Paris)* 9:338-339; 1976.

To aid in determining the type of surgery to be performed in 288 children with cholestatic jaundice, a discriminatory study was made to distinguish between the extrahepatic and intrahepatic forms of the disease. A comparison of four variables, including stool color after 10 days of observation, birth weight, age at the time of stool discoloration, and clinical features of the liver, yielded correct findings in 82% of the cases. When four histological variables were added to these parameters, the cholestasis was classified correctly in 85% of the cases. Needle biopsy provided no substantial aid in determining the type of surgery.

5036 SPLENIC PSEUDOSINUSES AND HEPATIC ANGIOMATOUS LESIONS: DISTINCTIVE FEATURES OF HAIRY CELL LEUKEMIA. (Eng.) Nanba, K.; Soban, E. J.; Bowling, M. C.; Berard, C. W. (Hiroshima Univ.

Sch. Medicine, Hiroshima, Japan). *Am. J. Clin. Pathol.* 67(5):415-426; 1977.

Tissues from 14 resected spleens from patients with hairy cell leukemia were examined for the presence of splenic pseudosinuses and hepatic angiomatous lesions. In all 14 spleens there were variably prominent distended spaces filled with RBC and resembling dilated sinuses. These structures appeared to be lined by hairy cells, and histochemical and enzymatic studies confirmed that they were pseudo-sinuses lacking the endothelial cells and ring fibers of normal splenic sinuses. These changes were not present in 4 normal spleens or in 10 spleens involved by other types of chronic leukemia, and appear to be qualitatively specific for hairy cell leukemia. In three of five hepatic biopsies, similar angiomatous lesions were present in multifocal clusters resembling hemangiomas. Their pathogenesis may be related to possible adherence of hairy cells to reticulum fibers in involved tissues.

5037 HEPATIC LYMPHANGIOMAS.

(Fre.) Debeugny, P. (No affiliation given). *Ann. Chir. Infant.* 17(5/6):419-423; 1976.

Three cases of hepatic lymphangiomas in children are presented. The first symptoms were noted between the ages of 6 and 18 months, and they included emesis, high body temperature, abdominal pain, and poor general condition. Hepatomegaly, the major symptom, was indolent in all three children. Radiology revealed digestive and renal opacification that showed only indirect signs of compression. Cholangiography in one patient revealed compression of the bile duct and gallbladder. Hepatic arteriography in two patients showed compression of the trunk and branches of the right hepatic artery. An α-fetoprotein test in two of the children was negative. Laparotomy with total excision of lesions was undertaken in two patients, and was extended to thoracophrenicectomy in one. The third patient underwent partial excision of the lesions. At 1-yr follow-up, the hepatic parenchyma was normal in two of the children. Postoperatively, persistent lymphatic drainage and hypogammaglobulinemia, which led to repeated infections, occurred in the third. When seen 3 yr later, he was still very susceptible to infection.

5038 HEPATIC DYSFUNCTION FOLLOWING TRAUMA: EXPERIMENTAL STUDIES.

Sarfeh, I. J.; Balint, J. A. (Albany Medical Coll., ME602 Dept. Surgery, Albany, NY 12208). *J. Surg. Res.* 22(4): 370-375; 1977.

To study the pathophysiology of post-traumatic hepatic dysfunction, male Sprague-Dawley rats were subjected to repeated deceleration injury under light ether anesthesia and the consequent hepatic and hemodynamic alterations were determined. Glycocholate infusion (7 mM, 2 ml/hr) enhanced bile flow and bile salt output in comparison to control values both before trauma (bile flow increased from 0.17 ± 0.02 to 0.27 ± 0.03 ml/hr/g liver and bile salt output increased from 1.19 ± 0.41 to 6.13 ± 1.30 μmol/hr/g liver) and after trauma (from 0.05 ± 0.01 to 0.09 ± 0.03 ml/hr/g for bile flow and from 0.55 ± 0.23 to 1.45 ± 0.44 μmol/hr/g for bile salt output). After trauma and a recovery period from the anesthesia, the total bile flow and bile salt output decreased significantly in both the saline-infused ($p<0.001$ and $p<0.01$) and glycocholate-infused animals ($p<0.01$ in both cases). The bile salt-independent fraction also decreased significantly following trauma (from a pretrauma value of 0.14 ± 0.02 ml/hr/g liver to 0.04 ± 0.02 ml/hr/g). The hepatic clearance rate of ^{3}H-glycocholate decreased significantly in the rats undergoing trauma, the half-time of disappearance increasing from 37 ± 2.9 to 53 ± 1.8 sec. Bile flow remained significantly below control levels for at least 6 hr in saline-infused animals but returned to control values by 24 hr. Sinusoidal hepatic blood flow behaved similarly to bile flow, but mean systemic arterial pressure returned to normal levels by 15 min after trauma following an initial fall. Hepatic ^{131}I-colloid lipid emulsion uptake was lower than control values after trauma but returned to near control values by 6 hr. Hematocrit and whole blood and plasma viscosity were not significantly affected by trauma. One hour after trauma, the livers showed centrilobular congestion and separation of liver cell cords by edema; these changes were still present at 24 hr. The results suggest that post-traumatic hepatic dysfunction results from hepatic ischemia due to altered splanchnic hemodynamics in shock.

5039 VENO-OCCLUSIVE DISEASE OF THE LIVER ASS
CIATED WITH ORAL CONTRACEPTIVES: CASE REPORT AND REVIEW OF THE LITERATURE.

(Eng.) Alpert, L. I. (Mt. Sinai Sch. Medicine, New York, NY). *Hum. Pathol.* 7(6):709-718; 1976.

The case of a 36-yr-old woman in whom veno-occlus
liver disease occurred after she had taken oral
contraceptives for 3 yr is reported. The patient
presented with ascites, occasional spider angioma
on the upper torso, whitened palms, and hepatospl
omegaly. Her prolonged course (1.5 yr from onset
symptoms until death) closely mimicked that of
chronic active hepatitis with progression to cirr
sis. In conflict with that diagnosis was the rel
tively minor alteration of liver function tests
(particularly the normal serum globulin level and
protein electrophoresis pattern), despite the dev
opment of portal hypertension with recurrent asci
The latter failed to improve after portacaval shu
Liver biopsies revealed severe central congestion
with progressive central fibrosis and prominent
sinusoidal engorgement resembling peliosis hepati
The presence of the well encapsulated adenomatous
nodule was interpreted at the time as evidence of
cirrhosis, further obfuscating the process of a
Budd-Chiari syndrome. Only at autopsy was the
widespread obliterative process involving central
sublobular, and hepatic veins observed. The typi
venous lesion was characterized by profound intin
proliferation and fibroplasia. Occasional evider

of sublobular vein recanalization evidenced the chronicity of this process. An unusual feature was widespread hepatocellular calcification in the absence of an elevated serum calcium level.

5040 STUDY OF AN EPIDEMIC OF VENOOCCLUSIVE DISEASE IN INDIA.

(Eng.) Tandon, R. K.; Tandon, B. N.; Tandon, H. D.; Bhatia, M. L.; Bhargava, S.; Lal, P.; Arora, R. R. (All-India Inst. Medical Sciences, Ansari Nagar, New Delhi-110016, India). *Gut* 17(11):849-855; 1976.

An epidemic of veno-occlusive disease occurring among 25 residents in a tribal district in central India during a 10-month period is described. The disease was manifested by rapidly developing ascites, and 11 patients died before they could be studied. The six patients (ages 12-38 yr) that could be hospitalized were studied for 2-17 months. The onset of the illness was characterized by mild continuous pain in the right upper quadrant and epigastrium, followed within 7-15 days by a drop in urinary output and rapidly filling ascites. The clinical features suggested an outflow tract obstruction such as a Budd-Chiari-like syndrome or veno-occlusive disease. Radiographic and hemodynamic studies demonstrated a combination of post- and perisinusoidal blocks, excluding the possibility of hepatic or portal vein obstruction. Liver dysfunction was indicated by the presence of a marked BSP retention (normal in only one patient) and mild to moderate hypoalbuminemia. After the ascites had been relieved, hepatomegaly and splenomegaly were noted in four and three patients, resp. The initial liver biopsies revealed zonal, centrilobular hemorrhagic necrosis. Subsequent biopsies showed replacement of the centrizonal areas of necrosis with radiating scars that created a picture of reversed lobulation. Five patients improved within 3-4 months on symptomatic treatment. One patient developed hepatic encephalopathy and died. Necropsy revealed an 800-g liver with severe centrizonal scarring associated with variable thickening and hepatic vein occlusion. Central vein occlusion and extensive centrilobular fibrosis were also present. The authors suggest that a vasospastic process occurred in these patients resulting from either circulating or fixed tissue toxin (from food) that affected both sinusoids and central veins so as to produce outflow tract obstruction at multiple sites.

5041 HETEROGENEITY OF WILSON'S DISEASE IN ISRAEL.

(Eng.) Passwell, J.; Adam, A.; Garfinkel, D.; Streiffler, M.; Cohen, B. E. (Chaim Sheba Medical Center, Tel-Hashomer, Israel). *Isr. J. Med. Sci.* 13(1):15-19; 1977.

The distribution and patterns of Wilson's disease among various ethnic populations were studied in 50 Israeli patients. The patients included 35 Jews (12 Ashkenazic, 3 Moroccan, 3 Iraqi, 8 Yemenite, 8 Iranian, and 1 Turkish), 9 Arabs, and 6 Druzes. Onset of the disease by the age of 10 yr was found in all but one of the Arab and Druze patients, but only nine Jews presented with symptoms at such an early age ($p<0.001$). Most of the non-Jewish patients showed an early onset of cirrhosis and an often rapidly fatal course. Male patients predominated in the Arab and Druze groups (11/15) and female patients in the Jewish group (16/23 non-Ashkenazic Jews and 7/12 Ashkenazic Jews). Genetic analysis of 20 families (37 affected patients out of 115 siblings) confirmed an autosomal recessive mode of inheritance. The ages of onset within sibling pairs were significantly correlated ($r=0.675$, $p<0.01$). The first two affected children in the families with three affected siblings were included in this calculation. The ages of onset in the three families with three affected siblings were also very similar. In one family, the ages of onset were 8, 8, and 5 yr; in the second, 10, 13, and 10; and in the third, 8, 5, and 8 yr. The very similar age of onset and type of disease within sibships and the varying ages of onset noted between the Arab and Jewish patients suggest that this disease is genetically heterogeneous.

5042 A METABOLIC DISORDER SIMILAR TO ZELLWEGER SYNDROME WITH HEPATIC ACATALASIA AND ABSENCE OF PEROXISOMES, ALTERED CONTENT AND REDOX STATE OF CYTOCHROMES, AND INFANTILE CIRRHOSIS WITH HEMOSIDEROSIS.

(Eng.) Versmold, H. T.; Bremer, H. J.; Herzog, V.; Siegel, G.; Bassewitz, D. B.; Irle, U.; *et al.* (Univ. Children's Hosp., D-8000 Munchen 2, W. Germany). *Eur. J. Pediatr.* 124(4): 261-275; 1977.

Ultrastructural, histochemical, pathologic, and spectroscopic studies were carried out in a patient with a cerebro-hepato-renal syndrome resembling the Zellweger syndrome (ZS). The visceral manifestations were those of the ZS; however, the child had muscular hypertonia, and he survived longer than patients with ZS (until the 2nd yr of life). The hepatocytes lacked peroxisomes, but contrary to the findings in one patient with ZS, contained smooth endoplasmic reticulum. No catalase was detected histochemically or spectroscopically. The mitochondria had normal succinate and glutamate respiration, and normal coupling of respiration to the phosphorylation potential. The cytochrome content was diminished to one-third, and the redox pattern of the respiratory chain in the controlled state was abnormal; cytochromes b and c were 5% and 23% reduced, resp. The oxygen affinity of cytochrome a_3 was normal. The findings exclude a defect in the nonheme iron protein region of the respiratory chain as found in ZS, but suggest a functional abnormality of cytochrome b in this patient.

Hyperbilirubinemic States

5060 LYSOSOMAL CHANGES IN LIVER TISSUE FROM PATIENTS WITH THE DUBIN-JOHNSON-SPRINZ SYNDROME. (Eng.) Seymour, C. A.; Neale, G.; Peters, T. J. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12 OHS, England). *Clin. Sci. Mol. Med.* 52(3):241-248; 1977.

The properties of the hepatic lysosomes of two patients with the Dubin-Johnson-Sprinz (DJS) syndrome were studied using analytical subcellular fractionation techniques, and the case reports of the patients are presented. Both patients, a 50-yr-old man and a 36-yr-old woman, were icteric and had abnormal BSP clearance (secondary rise to 58% and 20%, resp., at 2 hr). In both patients, all acid hydrolase activities (acid phosphatase, phosphodiesterase, α-glucosidase, α-galactosidase, α-mannosidase, *N*-acetyl-β-glucosaminidase, and β-glucuronidase) were elevated in comparison with those found in the liver biopsies of controls. When the distribution of lysosomal enzymes in the patients and controls was determined by fractionation, the acid hydrolase activity in the control subject mainly sedimented into the gradient, with broad peaks of activity extending over the density range 1.13-1.19; in the patients, most acid hydrolase activity remained in the sample layer and in the lighter part of the sucrose gradient. Melanin had a distribution similar to the lysosomal marker enzymes, suggesting that the lysosomes accumulate melanin. In a control subject, marker enzyme profiles showed clear separation of peroxisomes and mitochondria. There was no change in the distribution of peroxisomes or mitochondria in the patients. Although there are increased activities of lysosomal acid hydrolases in the liver tissue of these DJS syndrome patients, the integrity of these organelles is essentially normal and, therefore the accumulation of pigment would not be expected to initiate liver damage. The DJS syndrome is thus a benign type of secondary lysosomal storage disease.

5061 INDOCYANINE GREEN KINETICS IN NEWBORNS WITH NONHEMOLYTIC HYPERBILIRUBINEMIA. (Ger.) Heimann, G.; Roth, B.; Gladtke, E. (Universitats-Kinderklinik, Joseph-Stelzmann-Str. 9, D-5000 Koln 41, W. Germany). *Klin. Wochenschr.* 55(9): 451-456; 1977.

The kinetic patterns of indocyanine green (ICG) elimination from blood were determined after i.v. injection of the dye (2-4 mg/kg) in 22 newborns with nonhemolytic hyperbilirubinemia, 11 of whom were pretreated with phenobarbital (PH, 7.5 mg/kg/day x 5, p.o.). The other 11 newborns remained untreated and served as controls. Serum ICG was determined with a spectrophotometer. Average serum bilirubin concentration decreased significantly from 9.1 mg/100 ml to 4.7 mg/100 ml in the PH-treated newborns. Serum bilirubin concentrations did not change in the controls. PH-treated patients also had a significantly higher maximum elimination rate and Km (71.1 μM/min and 356.4 μM/min, resp.) than untreated controls (23.4 μM/min and 100 μM/min, resp.). After PH treatment, the ability of the liver to selectively eliminate the dye from the blood is probably increased. The results show that in newborns with nonhemolytic hyperbilirubinemia, the characteristic parameters of saturation kinetics are changed after PH treatment. The kinetics of ICG elimination support the hypothesis that cytoplasmatic proteins of liver should facilitate the uptake of organic anions, including bilirubin, into the liver cell. A deficiency of these transport protein may be one of the causes of the development of nonhemolytic hyperbilirubinemia in newborns.

5062 AGAR INGESTION COMBINED WITH PHOTOTHERAPY IN JAUNDICED NEWBORN INFANTS. (Eng.) Ebbesen, F.; Moller, J. (Rigshospitalet, Tagensvej 18, 2200 Copenhagen N, Denmark). *Biol. Neonate* 31(1/2): 7-9; 1977.

Studies were carried out in 49 jaundiced neonates to determine whether agar ingestion enhances the effect of phototherapy in reducing the serum bilirubin levels. Nonimmunized infants with a birth weight of more than 2,000 g were given phototherapy with white light for more than 36 hr. The average period of treatment was 61 hr. Twenty-four infants received 250 mg agar at the beginning of each meal at 3-hr intervals during phototherapy, and the remaining 25 infants received phototherapy alone. Serum bilirubin levels were decreased similarly in both groups. It is concluded that ingestion of agar does not supplement the effect of phototherapy.

5063 RENAL CLEARANCE OF GLUCURONATE-CONJUGATED BILIRUBIN FRACTIONS IN VARIOUS FORMS OF JAUNDICE. I. INTRODUCTION. NORMAL SUBJECTS. (Spa.) Candel Monserrate, I.; Diaz-Rubio Garcia, M. (Hospital Clinico San Carlos, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 46(1):1-12; 1975.

In a series of studies, monoglucuronated and diglucuronated (monoconjugated and diconjugated) bilirubin fractions were examined in the blood and urine of 14 healthy subjects and 47 patients with various types of jaundice. The following parameters were determined: direct- and indirect-reacting bilirubin in blood and urine; monoconjugated and diconjugated bilirubin fractions in blood and urine; pH, density, albumin content, and volume of urine; creatinine clearance; renal clearance of bilirubin; bromine; blood pH; and serum albumin, gammaglobulins, phosphatases. All 14 healthy subjects (ages 22-71; 8 men and 6 women) had a much higher percentage of monoconjugated bilirubin in the blood (average= 91.50 mg%) than in urine (average=37.28 mg%). Renal clearance of diconjugated bilirubin (average=9.559 cm^3/min) was considerably higher than clearance of the monoconjugated form (0.431 cm^3/min). Direct-reacting bilirubin was higher (average=0.28 mg%)

in the urine than was indirect-reacting (0.17 mg%). There were slight correlations between the amount of diconjugated bilirubin in the blood and renal clearance or pH. With exceptions, no correlations were seen between the conjugated fractions and the other parameters measured. The lack of correlation between creatinine clearance and bilirubin clearance suggests that, once filtered by the glomeruli, the bilirubin may be reabsorbed by the tubule.

5064 RENAL CLEARANCE OF GLUCURONATE-CONJUGATED BILIRUBIN FRACTIONS IN VARIOUS FORMS OF JAUNDICE. II. HEMOLYTIC JAUNDICE.

(Spa.) Candel Monserrate, I.; Diaz-Rubio Garcia, M. (Hospital Clinico San Carlos, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 46(2):131-144; 1975.

The results for six patients with hemolytic jaundice are reported from an extended study of renal clearance of glucuronate-conjugated bilirubin fractions. The following parameters were measured (52 determinations/patient): direct- and indirect-reacting bilirubin in blood and urine; pH, density, albumin content, and volume of urine; creatinine clearance; renal clearance of bilirubin; blood pH; and serum albumin, gammaglobulin, prothrombin, bromine, SGOT, SGPT, and alkaline and acid phosphatases. Correlation coefficients (r) were calculated for clearance of bilirubin fractions and the other parameters. The apparent predominance of diconjugated fraction clearance over clearance of the monoconjugated fraction decreased significantly ($p<0.05$) with respect to normal values. A direct correlation was shown between blood and urine levels of direct-reacting bilirubin and indirect-reacting bilirubin ($r=0.953$ and 0.940, resp.). A direct correlation was shown between urine direct- and indirect-reacting bilirubin and blood alkalinity ($r=0.849$ and $r=0.808$, resp.). A clear inverse correlation was found between clearance of diconjugated bilirubin and the level of plasma albumin ($r=-0.950$). No other correlations were demonstrated. In general, the patient with hemolytic jaundice show a better correlation than normal subjects between bilirubinemia and bilirubinuria.

5065 THE APPLICATION OF THE "LOJDA" METHOD FOR INTESTINAL LACTASE IN INTESTINAL BIOPSIES FROM JAUNDICED NEWBORN INFANTS.

(Eng.) Bakken, A. F. (Rikshospitalet, Univ. Oslo, Oslo, Norway). *Histochemistry* 51(2/3):253-255; 1977.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

5066 FULMINANT HEPATITIS AND DEVELOPMENT OF ARTIFICIAL LIVER SUPPORT.

(Eng.) Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London, S.E. 5, England). *Rush Presbyt. St. Luke's Med. Bull.* 15(2):132-143; 1976.

Two hundred cases of fulminant hepatitis were studied. Brain damage (cerebral edema), endotoxemic pulmonary infections, hemorrhagic diathesis, and localized erosions on the esophagus and stomach are reported to be common causes of death of these patients. The development of a biocompatible and efficient adsorbent perfusion system for protein-bound substances was investigated. Thirty-one patients were treated with charcoal (coated with acrylic hydrogel) hemoperfusion; 39% survived. Selective adherence of large platelets to coated charcoal is reported to result in prolonged bleeding and death. Use of cimetide or metiamide (sufficient to maintain an intragastric pH greater than 5) stopped bleeding in all of the fourteen patients studied ($p=0.001$). Use of immobilized carbon particles on a support polyester film combined with the Rhone-Poulenc dialysis machine is reported to be a satisfactory perfusion system and is under investigation. The possible use of albumin-coated XAD-7 is suggested because the resin has a high binding capacity for protein-bound metabolites so that both the supporting material and the coating should contribute to binding capacity.

5067 CURRENT STATUS OF POST-TRANSFUSION HEPATITIS.

(Eng.) Conrad, M. E. (Div. Hematology and Oncology, Univ. Alabama, Birmingham, AL 35294). *Am. J. Hematol.* 1(3):357-365; 1976.

The history of post-transfusion hepatitis is reviewe to describe the extent of the hepatitis problem associated with blood component therapy. Hepatitis A and hepatitis B are transmitted by both oral and parenteral routes. The discovery of hepatitis B surface antigen (HBsAg) provided an immunologic method for the identification of both patients and

rriers with hepatitis B. HBsAg is related to
agments of a lipoprotein membrane coating the sur-
ce of the complete virion particle. Three types
particles are reported in serum of the HBsAg-
sitive patient; small 20 mμ spheres, tubules 20
in diameter and up to 100 mμ long, and the more
mplex 42 mμ Dane particles that may be the com-
ete virion. The inner core of the Dane particles
ntains hepatitis B core antigen (HBcAg). Studies
serum for core antibody (anti-HBc) and HBsAg
e helpful in detection of hepatitis B. About 0.2%
the United States population are carriers of
sAg and probably are infectious. The prevalence
both HBsAg and anti-HBs is several fold greater
ong commercial blood donor populations than among
lunteer donors, among first time donors than re-
at donors, among men than women, among noncauca-
ans than caucasians, and among city dwellers than
rmers. The hepatitis associated antigen (HAA)
s presumed to the infectious agent for hepatitis A.
out 80% of post-transfusion hepatitis is caused by
e or more unidentified agents (non-A non-B
patitis). Good blood bank practices such as
e use only of carefully screened volunteer
nors, minimizing the number of donor units
ansfused, use of frozen washed RBC transfusions,
d prophylactic use of immune human serum gamma
obulin are suggested that might decrease both
e severity and occurrence of post-transfusion
patitis in blood recipients.

68 HEPATITIS DUE TO ASPIRIN. REPORT OF FOUR CASES.

(Spa.) Badrinas, F.; Niubo, R.;
lardell, J.; Nogues, F. (Ciudad Sanitaria "Prin-
pes de Espana," Hospitalet de Llobregat, Barcel-
a, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47(6):
6-817; 1976.

xic hepatitis due to high doses of acetosalicylic
id (3-4 g/day) is reported in four patients under
eatment for various disorders: a 29-yr-old patient
d acute idiopathic pericarditis (AP), a 32-yr-old
tient had systemic lupus erythematosus (SLE), and
patients (10 and 15 yr old) had rheumatic fever.
spirin was given for 9, 12, 6, and 30 days, resp.;
spepsia and elevated enzyme levels (glutamic oxa-
te transaminase, glutamic pyruvate transaminase, and
ctate dehydrogenase) were noted in all patients.
ne showed jaundice, and only the patient with
E had hepatomegaly. Four to 17 days after sus-
nding aspirin treatment, all symptoms of hepa-
toxicity disappeared. When aspirin was reintro-
ced at the same dose in the AP and SLE patients,
xic symptoms returned after 5 and 14 days, resp.
cause patients with these disorders are often
eated chronically with large doses of acetosal-
ylic acid, it is important to recognize the pos-
ble hepatotoxic effects.

069 DANTROLENE-ASSOCIATED HEPATIC INJURY. INCIDENCE AND CHARACTER.

(Eng.) Utili, R.;
itnott, J. K.; Zimmerman, H. J. (Veterans Admin.
sp., 50 Irving St., N.W., Washington, DC 20422).
astroenterology 72(4):610-616; 1977.

The incidence and character of dantrolene-induced liver injury is described. Hepatic injury during long-term dantrolene sodium therapy occurred in 19 of 1,044 patients monitored for at least 60 days. Six had icteric hepatitis (0.6%) and three died. After the marketing of the drug, an additional 31 cases of dantrolene-associated liver disease were available for analysis. Of these, 16 had icteric hepatitis with a favorable outcome, and 11 died. The injury was mainly hepatocellular with a pattern of acute or subacute hepatic disease or chronic active hepatitis. Analysis of 50 cases showed a 28% fatality rate. All the fatalities occurred in patients over 30 yr of age and after at least 2 months of therapy, with 57% of the cases exposed for at least 6 months. Eleven of the 14 fatalities occurred in females ($p<0.05$). No cases of hepatic disease occurred in patients exposed for less than 1 month or under the age of 10 yr. The majority of adverse reactions (71%) occurred between 1 and 6 months of therapy. Daily dosage of 300 mg or more was associated with higher incidence of hepatotoxic reactions and with the majority (85%) of the fatalities. This idiosyncratic hepatic injury does not appear to involve hypersensitivity to the drug. A careful assessment of the benefit-risk ratio in the therapeutic use of dantrolene sodium is proposed.

5070 CLINICAL ASPECTS OF HALOTHANE HEPATITIS.

(Ger.) Polterauer, P.; Brunner, H.; Grabner, G. (Ordinariat fur Gastroenterologie, Garnisongasse 13, A-1090 Vienna, Austria). *Wien. Med. Wochenschr.* 127(3):110-113; 1977.

Halothane hepatitis developed in a 53-yr-old woman after the agent was used as an anesthetic during extirpation of a breast node. She had previously developed a short-term fever when halothane was used during treatment of a fracture, but this was considered an exacerbation of chronic pyelitis in known nephrolithiasis. Six hours after the second procedure, the patient had a fever of 39.5 C associated with nausea and vomiting. Numerous bacteria, RBC, and WBC were found in the urinary sediment; these symptoms were thought to represent a urinary tract infection, for which trimethoprim-sulfamethoxazole was given. The fever persisted along with fatigue and epigastric pain. On the eighth postoperative day, pathological liver function parameters were found (bilirubin 0.8 mg%, SGOT 190 mU/ml, SGPT 270 mU/ml, alkaline phosphatase 166 mU/ml). The patient also had moderate eosinophilia with numerous WBC and *Proteus* in the urinary sediment. A liver scan showed a markedly enlarged liver with diffuse, inhomogeneous storage distribution. While the fever abated on day 10, transaminase levels peaked, and then remained constant between 120 and 170 mU/ml after a temporary fall. A liver biopsy revealed signs of toxic hepatitis, liver cell necroses, inflammatory infiltrates, and Kupffer cell activation in the lobules and multinuclear giant cells. Corticoid therapy with methylprednisolone (24 mg/day) was started on the 28th postoperative day. The transaminase and cholestasis enzyme levels returned to normal, and the patient was discharged on the 42nd postoperative day.

5071 MEGLUMINE IODIPAMIDE (CHOLOGRAFIN) HEPATOTOXICITY.

(Eng.) Sutherland, L. R.; Edwards, L. A.; Medline, A.; Wilkinson, R. W.; Connon, J. J. (Toronto Western Hosp., 399 Bathurst St., Toronto, Ontario M5T 2S8, Canada). *Ann. Intern. Med.* 86(4):437-439; 1977.

Two cases of meglumine iodipamide hepatotoxicity, confirmed by liver biopsy, are reported. The first patient, a 42-yr-old woman, underwent four i.v. cholangiograms for the investigation of nausea that occurred 1 yr following cholecystectomy. Forty milliliters of meglumine iodipamide were given over a 30-min period. She experienced nausea after the first cholangiogram and later had vomiting, dark urine, pale stools, and jaundice. After the last i.v. cholangiogram was carried out, she became febrile, and the liver was tender. Polymorphonuclear leukocytosis, elevated bilirubin, and elevated aspartate transaminase levels were present. A liver biopsy, carried out 4 days after the last cholangiogram, revealed marked centrilobular necrosis and abundant lipofuscin pigment in both altered hepatocytes and histiocytes in the involved areas. The second patient, a 43-yr-old man, who had recovered from viral hepatitis 5 yr earlier, underwent p.o. cholecystography for the evaluation of right upper quadrant pain. Two i.v. cholangiograms and a second p.o. cholecystogram were subsequently carried out. His symptoms were similar to those of the first patient, as were the liver biopsy findings; however, lipofuscin pigment was absent. A repeat liver biopsy 1 month later showed normal histology. Liver function tests are warranted in patients who experience nausea, vomiting, or fever after i.v. cholangiography.

5072 EARLY UNCONJUGATED HYPERBILIRUBINAEMIA AFTER PARACETAMOL OVERDOSAGE.

(Eng.) Davidson, A. R.; Rojas-Bueno, A.; Thompson, R. P. H.; Williams, R. (King's Coll. Hosp. and Medical Sch., London, England). *Scand. J. Gastroenterol.* 11:623-628; 1976.

A rapid increase in predominantly unconjugated bilirubin in the blood that was not due to hemolysis was observed in 38/60 patients who had ingested an overdose of paracetamol (10-125 g). Moderate liver damage (maximum bilirubin, 17-68 μM/1) was seen in 27 patients and severe liver damage (maximum bilirubin, >68 μM/1 in 11 patients. In all 38 patients, the plasma bilirubin levels rose during the first 3 days; in 5 patients who died, the peak bilirubin level was reached on the day of death (3-8 days after overdose). More than half of the mean
total bilirubin level was at all times indirect-
reacting and therefore predominantly unconjugated
Severe hemolysis was excluded by findings of norm
reticulocyte counts and the absence of a fall in
hemoglobin level. In experimental studies, male
albino Sprague-Dawley rats received either a norm
diet (controls), phenobarbitone (1 g/l drinking
water) for 4 days before sacrifice, or the same
phenobarbitone dose for 4 days followed by para-
cetamol treatment (3.5 g/kg by gastric lavage) 24
hr before sacrifice. The specific content of mic
somal cytochrome P.450 was increased by 71% after
phenobarbitone pretreatment (from 805 ± 374 to 1,
± 486 μmol/mg microsomal protein, $p < 0.125$), where
there was a 57% reduction of P.450 in phenobarbit
paracetamol-treated rats (to 586 ± 190 μmol/mg, p
0.001). Changes in total liver P.450 content wer
greater, being 428, 787, and 252 mmol/liver for c
trols, phenobarbitone-treated, and phenobarbitone
paracetamol-treated rats, resp. Phenobarbitone i
creased the mean specific activity of bilirubin g
curonyl transferase from 1.2 ± 0.34 to 2.2 ± 0.90
μmol bilirubin conjugated/g liver/hr ($p < 0.01$); wh
after phenobarbitone/paracetamol treatment, the m
specific activity of the transferase was 1.3 ± 0.
μmol/g/hr ($p < 0.01$). Changes in total bilirubin g
ronyl transferase activity in the liver were grea
being 9.8 ± 3.1, 56.7 ± 14.2, and 11.6 ± 8.4 μmol
conjugated bilirubin/liver/hr for controls, pheno
barbitone-treated, and phenobarbitone/paracetamol
treated rats, resp. ($p < 0.001$). Both P.450 and
glucuronyl transferase are enzymes of the endopla
mic reticulum, and it is suggested that early dam
age of the hepatic endoplasmic reticulum contribu
to the hyperbilirubinemia of paracetamol poisonin

5073 INFLUENCE OF POISONING ON LIVER AND INT
TINES.

(Ger.) Holle, G. (Pathologisch
Institut, Karl-Marx-Universitat, Liebigstr. 26, D
701 Leipzig, E. Germany). *Dtsch. Z. Verdau. Stof
wechselkr.* 36(2):49-58; 1976.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

5074 SIGNIFICANCE OF ISOENZYME STUDIES IN THE DIAGNOSIS OF LIVER DISEASES. PART 1: THEORETICAL CONCEPTS.

Graubaum, H. J.; Wagenknecht, C.; Schneider, G.; Schimmelpfennig, W.; Klimmt, G.; Baumgarten, R. (Institut fur Physiologische und Biologische Chemie, Bereich Medizin, Humboldt-Universitat, Hessische Strasse 3/4, DDR-104 Berlin, E. Germany). *Dtsch. Gesundheitsw.* 32(22):1015-1019; 1977.

The significance of isoenzyme studies in the diag
nosis of viral hepatitis and other liver disease

s discussed on the basis of correlations between ell structure and metabolism. Isoenzymes are artly organ- and organelle-specific. The isoenzyme attern is of diagnostic relevance because it is he result of regulatory mechanisms of enzyme synhesis and degradation and because the isoenzymes have reatly different serum elimination rates. The isonzymes of aldolase, LDH, and glutamic-oxalacetic ransaminase (GOT) were selected for their diagostic value. Cytoplasmic LDH isoenzymes show a cerain organ-specificity; synthesis of the H and M ypes depends on the oxygen supply. A direct relaionship was established between the H/M ratio and he rate of glycolysis. Aldolase isoenzymes are ighly organ-specific and changes in their pattern ere observed in the fetal liver and in hepatomas. he serum aldolase level is assumed to be a funcion of the rates of glycolysis and glyconeogenesis. he organelle-specific GOT isoenzymes may be able o differentiate between metabolic changes in the ytoplasm and in the mitochondria, which is imporant for evaluation of the extent of cell damage.

075 THE OCCURRENCE OF ORCEIN-POSITIVE HEPATOCELLULAR MATERIAL IN VARIOUS LIVER DISEASES.

Eng.) Salaspuro, M. P.; Sipponen, P.; Makkonen, H. Second Dept. Medicine, Univ. Helsinki, 00290 Helinki 29, Finland). *Scand. J. Gastroenterol.* 11(7): 77-681; 1976.

he occurrence of orcein-positive material was xamined in liver specimens from 103 patients with arious hepatic diseases and from 297 consecutive iver biopsies examined routinely. The specimens ere stained with orcein after oxidation with poassium permanganate. The 103 patients included 0 with Dubin-Johnson's syndrome, 5 with Gilbert's isease, 3 with hemochromatosis, 13 with acute heptitis, 14 with chronic persistent hepatitis, 12 ith alcoholic hepatitis, 9 with toxic hepatitis, 7 with cirrhosis, 4 with congenital biliary tresia, and 16 with extrahepatic biliary obstrucion. Orcein-positive material was demonstrated n two patients with long-standing biliary obstrucion without biliary cirrhosis and in three patients ith alcoholic liver disease characterized by intraepatic cholestasis of several months' duration. rcein positivity occurred in 22 of the 297 liver iopsy specimens in the second group of patients. istological cholestasis occurred in two cases of lcerative colitis with associated cholestatic liver isease, one case of cirrhosis combined with chronic ctive hepatitis, one case of biliary cirrhosis, nd three cases of alcoholic cirrhosis combined ith hepatoma. Other orcein-positive cases included rimary biliary cirrhosis, ulcerative colitis plus hronic active hepatitis, hepatogestosis, and lcoholic cirrhosis. Orcein-staining is useful in he differential diagnosis of primary biliary cirhosis; the only orcein-negative patient with priary biliary cirrhosis in this series had a very ild disease with low serum levels of alkaline hosphatase and minimal histological changes.

076 SIGNIFICANCE OF ISOENZYME STUDIES IN THE DIAGNOSIS OF LIVER DISEASES. PART 4: ACUTE HEPATITIS--POSSIBILITIES OF AN EVALUATION OF CURE ON THE BASIS OF LOAD TESTS.

(Ger.) Papsdorf, S.; Binus, R.; Hannig, B.; Wollmann, A.; Winkler, G. U.; *et al.* (Institut fur Physiologie und Biologische Chemie, Bereich Medizin, Humboldt-Universitat, Hessische Strasse 3/4, DDR-104 Berlin, E. Germany). *Dtsch. Gesundheitsw.* 32(26):1207-1211; 1977.

Aldolase (ALD), glutamic oxalacetic transaminase (GOT), and LDH activities of the venous blood were determined in 85 adults and 34 children during convalescence from acute hepatitis to assess the degree of recovery. Blood samples were taken before, immediately, and 24 hr after bicycle ergometer load test; the test was stopped as soon as a critical heart rate (160/min in adults, 210/min in children) was exceeded. The tests were performed 4-10 weeks after the manifestation of prodromal symptoms in adults and during the third to fifth weeks in children. It was possible to classify all patients as normal (normal isoenzyme activity before and after the load test), suspect (normal isoenzyme activity before and abnormal activity after the load test), or pathological (isoenzyme activity before and after the load test). Among the adults, the suspect group included 56% of all patients with protracted hepatitis; the other 44% were classed as pathological. In adults and in children, the altered isoenzyme activities were mainly cytoplasmic GOT and hepatic ALD and, sometimes, M-type LDH; mitochondrial GOT, type-H LDH, and muscular ALD were rarely affected.

5077 VERTICAL TRANSMISSION OF HEPATITIS-B SURFACE ANTIGEN.

(Eng.) Boxall, E. H. (East Birmingham Hosp., Birmingham B9 5ST, England). *Biomedicine* 26(1):12-15; 1977.

The transmission of hepatitis B virus from mother to infant, causing severe neonatal hepatitis, is reviewed. There is a large difference in the rate of vertical transmission in acute hepatitis and in the chronic carrier state. Transmission from a mother with acute hepatitis during pregnancy carries a greater risk for the infant in terms of acute hepatitis early in life or serious chronic liver disease with hepatitis B surface antigenemia. This risk is higher the closer the infection is to the time of delivery. Transmission from carrier mother falls into two distinct geographic groups. In the Eastern world, where the carrier rate is high, almost half the children born to carrier mothers also become carriers. In the Western world, only about 5% of children born to carriers also become carriers within the 1st yr of life. The reason for these differences may lie in different population distributions of e antigen, which has recently been shown to be associated with the transmission of the carrier state.

5078 HEPATITIS EPIDEMIOLOGY IN ZURICH CANTON AND VICINITY IN 1976.

(Ger.) Regli, P. J.; Joller-Jemelka, H. I.; Grob, P. J. (Abteilung fur Klinische Immunologie, Universitat Zurich, Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 107(22):769-779; 1977.

A total of 338 cases of acute viral hepatitis were diagnosed in Zurich Canton and vicinity in 1976. Hepatitis B (HB) was diagnosed in 188 cases, non-B hepatitis (NBH) in 150. The number of NBH cases decreased with age. Twenty-six patients had a history of hepatitis. There were no significant differences between men and women in the incidence of HB and in age at onset; the seasonal spread of the cases was also fairly uniform. Medical diagnostic and therapeutic procedures were thought to be responsible for viral transmission in 43% of the patients (73% of whom had HB). Travel to southern countries (Iraq, India, Africa) was the cause of hepatitis in 3 clusters of 16 cases, the only clusters observed in 1976. Sexual and social contact was the source of the disease in 56 patients, 33 of whom had HB. The estimated risk of hepatitis was highest for drug addicts (1.5%/yr), followed by medical personnel (0.3%-0.5%/yr), and travelers to high-risk countries (0.4%/yr).

5079 HEPATITIS B OUTBREAK TRACED TO AN ORAL SURGEON. (Eng.) Rimland, D.; Parkin, W. E.; Grayson, P. H.; Miller, B., Jr.; Schrack, W. D. (Emory Univ. Sch. Medicine, 69 Butler St., S.E., Atlanta, GA 30303). *N. Engl. J. Med.* 296(17):953-958; 1977.

A large outbreak of hepatitis B that was traced to a single hepatitis B surface antigen (HBsAg) carrier was investigated. Over a 4-yr period in a five-county area, 71 patients with clinical hepatitis B had dental work performed in the 2-6 months before their illness. Fifty-five cases were traced to a single oral surgeon. Seventy-nine percent of these patients were positive HBsAg, and most had no other recognized source of hepatitis. An investigation of the implicated dentist uncovered no gross inadequacies in instrument sterilization or general dental procedures; however, the dentist was found to be an asymptomatic carrier of HBsAg of the same subtype (*ay*) as 9/11 of his patients who had hepatitis and whose sera were tested. Since no HBsAg was found in the dentist's saliva, urine or feces, and since he admitted to having frequent cuts on his fingers, it is possible that a "hemo-oral" transmission of HBsAg produced hepatitis in his patients.

5080 SCREENING HOSPITAL PATIENTS FOR HEPATITIS B SURFACE ANTIGEN. (Eng.) Linnemann, C. C., Jr.; Hegg, M. E.; Ramundo, N.; Schiff, G. M. (231 Bethesda Ave., Cincinnati, OH 45267). *Am. J. Clin. Pathol.* 67(3):257-259; 1977.

The prevalence of hepatitis B surface antigen (HBsAg) and antibody to HBsAg (HBsAb) was determined in 1,026 patients to determine whether routine screening for this antigen and antibody is indicated. Fifteen patients (1.5%) were HBsAg-positive. The prevalence of HBsAg ranged from 4.8% (1/21) in the dialysis unit to 0% on the psychiatry service. Only 2 of the 15 patients had a diagnosis of hepatitis and, if these were excluded, the percentage of HBsAg-positive patients decreased to 1.3%. Of 971 patients tested, 211 (21.7%) had HBsAb. The percentages with antibody ranged from 13.4% on the obstetrics and gynecology
service to 29.8% on the medical service. Nineteen
percent of the dialysis patients had HBsAb. Routi
screening of all hospital admissions to detect the
1.3% with HBsAg does not seem justified by the ris
In addition, recognition of hepatitis B antigenemi
would not significantly alter the patient's care.
Routine measurement of SGOT on admission would be
less expensive and more effective in identifying
anicteric or chronic hepatitis.

5081 OCCURRENCE OF SUBTYPES OF HEPATITIS B
ANTIGEN IN ACUTE HEPATITIS AND CHRONIC
LIVER DISEASES. (Ger.) Buki, B.; Szalay, F.;
Nagylucskay, S.; Schvaab, E.; Magyar, D. (I. Medi-
zinische Klinik, Semmelweis-Universitat, Koranyi
u. 2/a, 1083 Budapest, Hungary). *Dtsch. Gesund-
heitsw.* 32(26):1215-1218; 1977.

Hepatitis B surface antigen (HBsAg)-positive sera
from 510 patients with acute viral hepatitis B an
sera from 113 patients with chronic liver disease
were analyzed electrophoretically for HBsAg sub-
types. In acute hepatitis, *ad* and *ay* subtypes we
found in 229 and 281 cases, resp.; among 353 ic-
teric cases, the *ad* subtype was found in 138, *ay*
215; among the 157 anicteric cases, *ad* and *ay* wer
found in 91 and 66 cases, resp. In the age group
0-10 yr, *ad* and *ay* were found in 41 and 46 cases,
resp., versus 61 and 64 in the group aged 11-20 y
and 86 in the group aged 21-40 yr, 44 and 56 in t
group aged 41-60 yr, and 23 and 29 in those >60 y
Twenty patients remained positive after the acute
phase; six had *ad*, and 14, *ay*. Thirty-one of the
113 patients with chronic liver diseases were HBs
positive. Seven had *ad* (1/29 in chronic persisti
hepatitis, 0/6 in chronic aggressive hepatitis, 4
in cryptogenic cirrhosis, 1/13 in alcoholic fatty
degeneration, 1/20 in alcoholic cirrhosis, and 0/
in other liver diseases). Twenty-four patients h
subtype *ay* (6/29 in chronic persisting hepatitis,
2/6 in chronic aggressive hepatitis, 10/26 in
cryptogenic cirrhosis, 1/13 in alcoholic fatty de
generation, 2/20 in alcoholic cirrhosis, and 3/19
in other liver diseases). No correlation was fou
between subtype and the seriousness of the clinic
chemical, immunological, and histological changes
chronic liver diseases.

5082 HEPATITIS B SURFACE ANTIGEN (HBsAg) IN
HOSPITALIZED CHILDREN. (Ger.) Meier,
Ch.; Frey-Wettstein, M. (Blutspendezentrum Limmat
CH-8952 Schlieren/Zurich, Switzerland). *Helv.
Paediatr. Acta* 32(1):11-19; 1977.

Serum samples from 1,940 children hospitalized fo
various conditions were analyzed for hepatitis B
surface antigen (HBsAg). Sera from 26 patients w
found to be HBsAg-positive by hemagglutination an
radioimmunoassay; the positive patients included
3 with hepatitis B. Thus, the incidence of
positive cases that were hepatitis B-independent
was 1.19%. This incidence was 1.7% among childre
at a large university children's hospital and 0.6
among those at small regional hospitals. The age
brackets 0-4, 5-8, and 9-12 yr had six positive

children each, and five were in the age bracket 13-16 yr; the corresponding percentages were 1.03%, 1.25%, 1.60%, and 1.68%, showing a slowly rising tendency with age. Thirteen of the positive children were hospitalized for blood transfusion, 10 for malformations, 5 for cardiac catheterization, 3 each for renal diseases and immune deficiency, 6 for neurological disorders, 9 for perinatal disturbances, and 8 for other reasons. Vertical transmission of hepatitis B virus from pregnant or nursing mothers to their children could not be found. Infection in early childhood appears probable at least in some of the cases.

5083 SUBTYPING OF HEPATITIS B SURFACE ANTIGEN AND ANTIBODY BY RADIOIMMUNOASSAY. (Eng.)

Hoofnagle, J. H.; Gerety, R. J.; Smallwood, L. A.; Barker, L. F. (Bureau Biologics, Food and Drug Admin., Bethesda, MD). *Gastroenterology* 72(2): 290-296; 1977.
